Valid	Float/High-Z	Switch Disable High impedance

**APPLICATION INFORMATION**

**Over Voltage Protection**

Over voltage protection turns the switch off if the inputs HSD+/HSD- rise above the over voltage trip threshold.

**Under Voltage Lockout**

The under-voltage lockout on V<sub>DD</sub> pin turns the switch off if the V<sub>DD</sub> voltage drops below the lockout threshold. With the SELpin active, the input voltage rising above the UVLO threshold releases the lockout and enables the switch.

**Tri-State Input Control Pin (SEL)**

The SEL pin can be tri-stated to disable the switch to save power, there are a few ways to achieve this. If the SEL pin is controlled by GPIO in the system, if the GPIO pin has a High-Z state where the impedance of the High-Z state is

larger than 2.5 MΩ the switch will recognize the High-Z state and disable the switch. If the system does not have GPIO that supports High-Z state, the user can utilize 2 MOSFETs or a Logic Device to achieve the same result.

*For GPIO*

The SEL pin function below:

- If the input is pulled up with less than 50 kΩ it will be considered as Logic High
- If the input is pulled down with less than 50 kΩ it will be consider as Logic Low
- If the input is pulled up or down with more than 2.5 MΩ it will be consider as float/High-Z

When 2x UART signals are switched over FSUSB242, both 100 ohm series resistor and 1 nF bypass capacitors are recommended in the common switch path as above. If FSUSB242 is used to switch USB and UART signals, connect UART signals to HSD1.

Functional operation above the stresses listed in the Recommended Operating Ranges is not implied. Extended exposure to stresses beyond the Recommended Operating Ranges limits may affect device reliability.

2. The switch swing voltage is based on the OVP trip level, and when OVP triggers the switch will be disabled to protect the host and no longer in the standard operating condition, once over voltage is removed the device will automatically recover back to normal condition.
