

# SAM E70/S70/V70/V71

---

---

## 32-bit Arm Cortex-M7 MCUs with FPU, Audio and Graphics Interfaces, High-Speed USB, Ethernet, and Advanced Analog

---

---

### Features

---

#### Core

- Arm® Cortex®-M7 running at up to 300 MHz
- 16 Kbytes of I-Cache and 16 Kbytes of D-Cache with Error Code Correction (ECC)
- Single-precision and double-precision HW Floating Point Unit (FPU)
- Memory Protection Unit (MPU) with 16 zones
- DSP Instructions, Thumb®-2 Instruction Set
- Embedded Trace Module (ETM) with instruction trace stream, including Trace Port Interface Unit (TPIU)

#### Memories

- Up to 2048 Kbytes embedded Flash with unique identifier and user signature for user-defined data
- Up to 384 Kbytes embedded Multi-port SRAM
- Tightly Coupled Memory (TCM)
- 16 Kbytes ROM with embedded Bootloader routines (UART0, USB) and IAP routines
- 16-bit Static Memory Controller (SMC) with support for SRAM, PSRAM, LCD module, NOR and NAND Flash with on-the-fly scrambling

#### System

- Embedded voltage regulator for single-supply operation
- Power-on-Reset (POR), Brown-out Detector (BOD) and Dual Watchdog for safe operation
- Quartz or ceramic resonator oscillators: 3 MHz to 20 MHz main oscillator with failure detection, 12 MHz or 16 MHz needed for USB operations. Optional low-power 32.768 kHz for RTC or device clock
- RTC with Gregorian calendar mode, waveform generation in low-power modes
- RTC counter calibration circuitry compensates for 32.768 kHz crystal frequency variations
- 32-bit low-power Real-time Timer (RTT)
- High-precision Main RC oscillator with 12 MHz default frequency
- 32.768 kHz crystal oscillator or Slow RC oscillator as source of low-power mode device clock (SLCK)
- One 500 MHz PLL for system clock, one 480 MHz PLL for USB high-speed operations
- Temperature Sensor
- One dual-port 24-channel central DMA Controller (XDMAC)

#### Low-Power Features

- Low-power sleep, wait and backup modes, with typical power consumption down to 1.1  $\mu$ A in Backup mode with RTC, RTT and wakeup logic enabled
- Ultra low-power RTC and RTT
- 1 Kbyte of backup RAM (BRAM) with dedicated regulator

#### Peripherals

- One Ethernet MAC (GMAC) 10/100 Mbps in MII mode and RMII with dedicated DMA. IEEE® 1588 PTP frames and 802.3az Energy-efficiency support. Ethernet AVB support with IEEE802.1AS Timestamping and IEEE802.1Qav credit-based traffic-shaping hardware support.

- USB 2.0 Device/Mini Host High-speed (USBHS) at 480 Mbps, 4-Kbyte FIFO, up to 10 bidirectional endpoints, dedicated DMA
- 12-bit ITU-R BT. 601/656 Image Sensor Interface (ISI)
- Two host Controller Area Networks (MCAN) with Flexible Data Rate (CAN-FD) with SRAM-based mailboxes, time-triggered and event-triggered transmission
- MediaLB<sup>®</sup> device with 3-wire mode, up to 1024 x Fs speed, supporting MOST25 and MOST50 networks
- Three USARTs, USART0, USART1, USART2, support LIN mode, ISO7816, IrDA<sup>®</sup>, RS-485, SPI, Manchester and Modem modes; USART1 supports LON mode.
- Five 2-wire UARTs with SleepWalking<sup>™</sup> support
- Three Two-Wire Interfaces (TWIHS) (I<sup>2</sup>C-compatible) with SleepWalking support
- Quad I/O Serial Peripheral Interface (QSPI) interfacing up to 256 MB Flash and with eExecute-In-Place and on-the-fly scrambling
- Two Serial Peripheral Interfaces (SPI)
- One Serial Synchronous Controller (SSC) with I<sup>2</sup>S and TDM support
- Two Inter-IC Sound Controllers (I2SC)
- One High-speed Multimedia Card Interface (HSMCI) (SDIO/SD Card/e.MMC)
- Four Three-Channel 16-bit Timer/Counters (TC) with Capture, Waveform, Compare and PWM modes, constant on time. Quadrature decoder logic and 2-bit Gray Up/Down Counter for stepper motor
- Two 4-channel 16-bit PWMs with complementary outputs, Dead Time Generator and eight fault inputs per PWM for motor control, two external triggers to manage power factor correction (PFC), DC-DC and lighting control
- Two Analog Front-End Controllers (AFEC), each supporting up to 12 channels with differential input mode and programmable gain stage, allowing dual sample-and-hold (S&H) at up to 1.7 Msps. Offset and gain error correction feature.
- One 2-channel, 12-bit, 1 Msps-per-channel Digital-to-Analog Controller (DAC) with Differential and Over Sampling modes
- One Analog Comparator Controller (ACC) with flexible input selection, selectable input hysteresis

## Cryptography

- True Random Number Generator (TRNG)
- AES: 256-bit, 192-bit, 128-bit Key Algorithm, Compliant with FIPS PUB-197 Specifications
- Integrity Check Monitor (ICM). Supports Secure Hash Algorithm SHA1, SHA224 and SHA256.

## I/O

- Up to 114 I/O lines with external interrupt capability (edge- or level-sensitivity), debouncing, glitch filtering and On-die Series Resistor Termination
- Five Parallel Input/Output Controllers (PIO)

## Voltage

- Single supply voltage from 3.0V to 3.6V for Qualification AEC - Q100 Grade 2 Devices
- Single Supply voltage from 1.7V to 3.6V for Industrial Temperature Devices

## Packages

- LQFP144, 144-lead LQFP, 20x20 mm, pitch 0.5 mm
- LFBGA144, 144-ball LFBGA, 10x10 mm, pitch 0.8 mm
- TFBGA144, 144-ball TFBGA, 10x10 mm, pitch 0.8 mm
- UFBGA144, 144-ball UFBGA, 6x6 mm, pitch 0.4 mm
- LQFP100, 100-lead LQFP, 14x14 mm, pitch 0.5 mm
- TFBGA100, 100-ball TFBGA, 9x9 mm, pitch 0.8 mm
- VFBGA100, 100-ball VFBGA, 7x7 mm, pitch 0.65 mm
- LQFP64, 64-lead LQFP, 10x10 mm, pitch 0.5 mm
- QFN64, 64-pad QFN 9x9 mm, pitch 0.5 mm with wettable flanks

## Table of Contents

|  |    |
|--|----|
| Features.....  | 1  |
| 1. Configuration Summary.....                        | 13 |
| 2. Ordering Information.....                         | 15 |
| 3. Block Diagram.....                                | 16 |
| 4. Signal Description.....                           | 20 |
| 5. Automotive Quality Grade.....                     | 27 |
| 6. Package and Pinout.....                           | 28 |
| 6.1. 144-lead Packages.....                          | 28 |
| 6.2. 144-lead Package Pinout.....                    | 29 |
| 6.3. 100-lead Packages.....                          | 35 |
| 6.4. 100-lead Package Pinout.....                    | 36 |
| 6.5. 64-lead Package.....                            | 39 |
| 6.6. 64-lead Package Pinout.....                     | 39 |
| 7. Power Considerations.....                         | 43 |
| 7.1. Power Supplies.....                             | 43 |
| 7.2. Power Constraints.....                          | 43 |
| 7.3. Voltage Regulator.....                          | 44 |
| 7.4. Backup SRAM Power Switch.....                   | 44 |
| 7.5. Active Mode.....                                | 45 |
| 7.6. Low-power Modes.....                            | 45 |
| 7.7. Wakeup Sources.....                             | 47 |
| 7.8. Fast Startup.....                               | 47 |
| 8. Input/Output Lines.....                           | 48 |
| 8.1. General-Purpose I/O Lines.....                  | 48 |
| 8.2. System I/O Lines.....                           | 48 |
| 8.3. NRST Pin.....                                   | 50 |
| 8.4. ERASE Pin.....                                  | 50 |
| 9. Interconnect.....                                 | 51 |
| 10. Product Mapping.....                             | 52 |
| 11. Memories.....                                    | 53 |
| 11.1. Embedded Memories.....                         | 53 |
| 11.2. External Memories.....                         | 59 |
| 12. Event System.....                                | 60 |
| 12.1. Embedded Characteristics.....                  | 60 |
| 12.2. Real-time Event Mapping.....                   | 60 |
| 13. System Controller.....                           | 64 |
| 13.1. System Controller and Peripherals Mapping..... | 64 |

|  |     |
|--|-----|
| 13.2. Power-on-Reset, Brownout and Supply Monitor..... | 64  |
| 13.3. Reset Controller.....                            | 64  |
| 14. Peripherals.....                                   | 65  |
| 14.1. Peripheral Identifiers.....                      | 65  |
| 14.2. Peripheral Signal Multiplexing on I/O Lines..... | 67  |
| 15. Arm Cortex-M7 .....                                | 68  |
| 15.1. Arm Cortex-M7 Configuration.....                 | 68  |
| 16. Debug and Test Features.....                       | 69  |
| 16.1. Description.....                                 | 69  |
| 16.2. Embedded Characteristics.....                    | 69  |
| 16.3. Associated Documents.....                        | 69  |
| 16.4. Debug and Test Block Diagram.....                | 70  |
| 16.5. Debug and Test Pin Description.....              | 70  |
| 16.6. Application Examples.....                        | 71  |
| 16.7. Functional Description.....                      | 72  |
| 17. SAM-BA Boot Program.....                           | 76  |
| 17.1. Description.....                                 | 76  |
| 17.2. Embedded Characteristics.....                    | 76  |
| 17.3. Hardware and Software Constraints.....           | 76  |
| 17.4. Flow Diagram.....                                | 76  |
| 17.5. Device Initialization.....                       | 77  |
| 17.6. SAM-BA Monitor.....                              | 77  |
| 18. Fast Flash Programming Interface (FFPI).....       | 81  |
| 18.1. Description.....                                 | 81  |
| 18.2. Embedded Characteristics.....                    | 81  |
| 18.3. Parallel Fast Flash Programming.....             | 81  |
| 19. Bus Matrix (MATRIX).....                           | 89  |
| 19.1. Description.....                                 | 89  |
| 19.2. Embedded Characteristics.....                    | 89  |
| 19.3. Functional Description.....                      | 91  |
| 19.4. Register Summary.....                            | 95  |
| 20. USB Transmitter Macrocell Interface (UTMI).....    | 112 |
| 20.1. Description.....                                 | 112 |
| 20.2. Embedded Characteristics.....                    | 112 |
| 20.3. Register Summary.....                            | 113 |
| 21. Chip Identifier (CHIPID).....                      | 116 |
| 21.1. Description.....                                 | 116 |
| 21.2. Embedded Characteristics.....                    | 116 |
| 21.3. Register Summary.....                            | 118 |
| 22. Enhanced Embedded Flash Controller (EEFC).....     | 123 |
| 22.1. Description.....                                 | 123 |

|   |     |
|---|-----|
| 22.2. Embedded Characteristics.....               | 123 |
| 22.3. Product Dependencies.....                   | 123 |
| 22.4. Functional Description.....                 | 123 |
| 22.5. Register Summary.....                       | 141 |
| 23. Supply Controller (SUPC).....                 | 149 |
| 23.1. Description.....                            | 149 |
| 23.2. Embedded Characteristics.....               | 149 |
| 23.3. Block Diagram.....                          | 150 |
| 23.4. Functional Description.....                 | 151 |
| 23.5. Register Summary.....                       | 162 |
| 24. Watchdog Timer (WDT).....                     | 173 |
| 24.1. Description.....                            | 173 |
| 24.2. Embedded Characteristics.....               | 173 |
| 24.3. Block Diagram.....                          | 173 |
| 24.4. Functional Description.....                 | 174 |
| 24.5. Register Summary.....                       | 176 |
| 25. Reinforced Safety Watchdog Timer (RSWDT)..... | 181 |
| 25.1. Description.....                            | 181 |
| 25.2. Embedded Characteristics.....               | 181 |
| 25.3. Block Diagram.....                          | 182 |
| 25.4. Functional Description.....                 | 182 |
| 25.5. Register Summary.....                       | 184 |
| 26. Reset Controller (RSTC).....                  | 189 |
| 26.1. Description.....                            | 189 |
| 26.2. Embedded Characteristics.....               | 189 |
| 26.3. Block Diagram.....                          | 189 |
| 26.4. Functional Description.....                 | 190 |
| 27. Real-time Clock (RTC).....                    | 200 |
| 27.1. Description.....                            | 200 |
| 27.2. Embedded Characteristics.....               | 200 |
| 27.3. Block Diagram.....                          | 200 |
| 27.4. Product Dependencies.....                   | 201 |
| 27.5. Functional Description.....                 | 201 |
| 27.6. Register Summary.....                       | 209 |
| 28. Real-time Timer (RTT).....                    | 227 |
| 28.1. Description.....                            | 227 |
| 28.2. Embedded Characteristics.....               | 227 |
| 28.3. Block Diagram.....                          | 227 |
| 28.4. Functional Description.....                 | 227 |
| 28.5. Register Summary.....                       | 230 |
| 29. General Purpose Backup Registers (GPBR).....  | 236 |
| 29.1. Description.....                            | 236 |

|   |     |
|---|-----|
| 29.2. Embedded Characteristics.....                         | 236 |
| 29.3. Register Summary.....                                 | 237 |
| 30. Clock Generator.....                                    | 239 |
| 30.1. Description.....                                      | 239 |
| 30.2. Embedded Characteristics.....                         | 239 |
| 30.3. Block Diagram.....                                    | 240 |
| 30.4. Slow Clock.....                                       | 240 |
| 30.5. Main Clock.....                                       | 241 |
| 30.6. PLLA Clock.....                                       | 245 |
| 30.7. UTMI PLL Clock.....                                   | 246 |
| 31. Power Management Controller (PMC).....                  | 247 |
| 31.1. Description.....                                      | 247 |
| 31.2. Embedded Characteristics.....                         | 247 |
| 31.3. Block Diagram.....                                    | 248 |
| 31.4. Host Clock Controller.....                            | 248 |
| 31.5. Processor Clock Controller.....                       | 248 |
| 31.6. SysTick External Clock.....                           | 248 |
| 31.7. USB Full-speed Clock Controller.....                  | 249 |
| 31.8. Core and Bus Independent Clocks for Peripherals.....  | 249 |
| 31.9. Peripheral and Generic Clock Controller.....          | 249 |
| 31.10. Asynchronous Partial Wakeup.....                     | 250 |
| 31.11. Free-running Processor Clock.....                    | 252 |
| 31.12. Programmable Clock Output Controller.....            | 252 |
| 31.13. Fast Startup.....                                    | 252 |
| 31.14. Startup from Embedded Flash.....                     | 254 |
| 31.15. Main Crystal Oscillator Failure Detection.....       | 254 |
| 31.16. 32.768 kHz Crystal Oscillator Frequency Monitor..... | 255 |
| 31.17. Recommended Programming Sequence.....                | 255 |
| 31.18. Clock Switching Details.....                         | 257 |
| 31.19. Register Write Protection.....                       | 260 |
| 31.20. Register Summary.....                                | 262 |
| 32. Parallel Input/Output Controller (PIO).....             | 314 |
| 32.1. Description.....                                      | 314 |
| 32.2. Embedded Characteristics.....                         | 314 |
| 32.3. Block Diagram.....                                    | 315 |
| 32.4. Product Dependencies.....                             | 316 |
| 32.5. Functional Description.....                           | 316 |
| 32.6. Register Summary.....                                 | 329 |
| 33. External Bus Interface.....                             | 390 |
| 33.1. Description.....                                      | 390 |
| 33.2. Embedded Characteristics.....                         | 390 |
| 33.3. EBI Block Diagram.....                                | 391 |
| 33.4. I/O Lines Description.....                            | 391 |
| 33.5. Application Example.....                              | 392 |

|  |     |
|--|-----|
| 34. Static Memory Controller (SMC).....          | 396 |
| 34.1. Description.....                           | 396 |
| 34.2. Embedded Characteristics.....              | 396 |
| 34.3. I/O Lines Description.....                 | 396 |
| 34.4. Multiplexed Signals.....                   | 397 |
| 34.5. Product Dependencies.....                  | 397 |
| 34.6. External Memory Mapping.....               | 397 |
| 34.7. Connection to External Devices.....        | 398 |
| 34.8. Application Example.....                   | 401 |
| 34.9. Standard Read and Write Protocols.....     | 403 |
| 34.10. Scrambling/Unscrambling Function.....     | 410 |
| 34.11. Automatic Wait States.....                | 411 |
| 34.12. Data Float Wait States.....               | 414 |
| 34.13. External Wait.....                        | 417 |
| 34.14. Slow Clock Mode.....                      | 421 |
| 34.15. Asynchronous Page Mode.....               | 423 |
| 34.16. Register Summary.....                     | 426 |
| 35. DMA Controller (XDMAC).....                  | 438 |
| 35.1. Description.....                           | 438 |
| 35.2. Embedded Characteristics.....              | 438 |
| 35.3. Block Diagram.....                         | 439 |
| 35.4. DMA Controller Peripheral Connections..... | 439 |
| 35.5. Functional Description.....                | 441 |
| 35.6. Linked List Descriptor Operation.....      | 444 |
| 35.7. XDMAC Maintenance Software Operations..... | 449 |
| 35.8. XDMAC Software Requirements.....           | 449 |
| 35.9. Register Summary.....                      | 451 |
| 36. Image Sensor Interface.....                  | 496 |
| 36.1. Description.....                           | 496 |
| 36.2. Embedded Characteristics.....              | 497 |
| 36.3. Block Diagram.....                         | 497 |
| 36.4. Product Dependencies.....                  | 497 |
| 36.5. Functional Description.....                | 498 |
| 36.6. Register Summary.....                      | 507 |
| 37. GMAC - Ethernet MAC.....                     | 541 |
| 37.1. Description.....                           | 541 |
| 37.2. Embedded Characteristics.....              | 541 |
| 37.3. Block Diagram.....                         | 542 |
| 37.4. Signal Interface.....                      | 542 |
| 37.5. Product Dependencies.....                  | 543 |
| 37.6. Functional Description.....                | 543 |
| 37.7. Programming Interface.....                 | 569 |
| 37.8. Register Summary.....                      | 574 |
| 38. USB High-Speed Interface (USBHS).....        | 713 |

|   |      |
|---|------|
| 38.1. Description.....                                | 713  |
| 38.2. Embedded Characteristics.....                   | 713  |
| 38.3. Block Diagram.....                              | 714  |
| 38.4. Signal Description.....                         | 714  |
| 38.5. Product Dependencies.....                       | 714  |
| 38.6. Functional Description.....                     | 715  |
| 38.7. Register Summary.....                           | 737  |
| 39. High-Speed Multimedia Card Interface (HSMCI)..... | 885  |
| 39.1. Description.....                                | 885  |
| 39.2. Embedded Characteristics.....                   | 885  |
| 39.3. Block Diagram.....                              | 886  |
| 39.4. Application Block Diagram.....                  | 886  |
| 39.5. Pin Name List.....                              | 887  |
| 39.6. Product Dependencies.....                       | 887  |
| 39.7. Bus Topology.....                               | 887  |
| 39.8. High-Speed Multimedia Card Operations.....      | 889  |
| 39.9. SD/SDIO Card Operation.....                     | 898  |
| 39.10. CE-ATA Operation.....                          | 898  |
| 39.11. HSMCI Boot Operation Mode.....                 | 899  |
| 39.12. HSMCI Transfer Done Timings.....               | 900  |
| 39.13. Register Write Protection.....                 | 901  |
| 39.14. Register Summary.....                          | 902  |
| 40. Serial Peripheral Interface (SPI).....            | 931  |
| 40.1. Description.....                                | 931  |
| 40.2. Embedded Characteristics.....                   | 931  |
| 40.3. Block Diagram.....                              | 932  |
| 40.4. Application Block Diagram.....                  | 932  |
| 40.5. Signal Description.....                         | 933  |
| 40.6. Product Dependencies.....                       | 933  |
| 40.7. Functional Description.....                     | 933  |
| 40.8. Register Summary.....                           | 946  |
| 41. Quad Serial Peripheral Interface (QSPI).....      | 963  |
| 41.1. Description.....                                | 963  |
| 41.2. Embedded Characteristics.....                   | 963  |
| 41.3. Block Diagram.....                              | 964  |
| 41.4. Signal Description.....                         | 964  |
| 41.5. Product Dependencies.....                       | 964  |
| 41.6. Functional Description.....                     | 965  |
| 41.7. Register Summary.....                           | 981  |
| 42. Two-wire Interface (TWIHS).....                   | 1003 |
| 42.1. Description.....                                | 1003 |
| 42.2. Embedded Characteristics.....                   | 1003 |
| 42.3. List of Abbreviations.....                      | 1004 |
| 42.4. Block Diagram.....                              | 1004 |
| 42.5. I/O Lines Description.....                      | 1004 |

|  |      |
|--|------|
| 42.6. Product Dependencies.....  | 1005 |
| 42.7. Functional Description.....  | 1005 |
| 42.8. Register Summary.....  | 1042 |
| 43. Synchronous Serial Controller (SSC).....                             | 1069 |
| 43.1. Description.....   | 1069 |
| 43.2. Embedded Characteristics.....                                      | 1069 |
| 43.3. Block Diagram.....   | 1070 |
| 43.4. Application Block Diagram.....                                     | 1070 |
| 43.5. SSC Application Examples.....                                      | 1070 |
| 43.6. Pin Name List.....   | 1072 |
| 43.7. Product Dependencies.....  | 1072 |
| 43.8. Functional Description.....  | 1073 |
| 43.9. Register Summary.....  | 1084 |
| 44. Inter-IC Sound Controller (I2SC).....                                | 1112 |
| 44.1. Description.....   | 1112 |
| 44.2. Embedded Characteristics.....                                      | 1112 |
| 44.3. Block Diagram.....   | 1113 |
| 44.4. I/O Lines Description.....   | 1113 |
| 44.5. Product Dependencies.....  | 1113 |
| 44.6. Functional Description.....  | 1114 |
| 44.7. I2SC Application Examples.....                                     | 1118 |
| 44.8. Register Summary.....  | 1122 |
| 45. Universal Synchronous Asynchronous Receiver Transceiver (USART)..... | 1137 |
| 45.1. Description.....   | 1137 |
| 45.2. Features.....  | 1137 |
| 45.3. Block Diagram.....   | 1139 |
| 45.4. I/O Lines Description.....   | 1139 |
| 45.5. Product Dependencies.....  | 1140 |
| 45.6. Functional Description.....  | 1140 |
| 45.7. Register Summary.....  | 1188 |
| 46. Universal Asynchronous Receiver Transmitter (UART).....              | 1260 |
| 46.1. Description.....   | 1260 |
| 46.2. Embedded Characteristics.....                                      | 1260 |
| 46.3. Block Diagram.....   | 1260 |
| 46.4. Product Dependencies.....  | 1261 |
| 46.5. Functional Description.....  | 1261 |
| 46.6. Register Summary.....  | 1270 |
| 47. Media Local Bus (MLB).....   | 1284 |
| 47.1. Description.....   | 1284 |
| 47.2. Embedded Characteristics.....                                      | 1285 |
| 47.3. Block Diagram.....   | 1285 |
| 47.4. Signal Description.....  | 1286 |
| 47.5. Product Dependencies.....  | 1286 |
| 47.6. Functional Description.....  | 1287 |

|  |      |
|--|------|
| 47.7. Register Summary.....                            | 1328 |
| 48. Controller Area Network (MCAN).....                | 1362 |
| 48.1. Description.....                                 | 1362 |
| 48.2. Embedded Characteristics.....                    | 1362 |
| 48.3. Block Diagram.....                               | 1363 |
| 48.4. Product Dependencies.....                        | 1363 |
| 48.5. Functional Description.....                      | 1364 |
| 48.6. Register Summary.....                            | 1389 |
| 49. Timer Counter (TC).....                            | 1449 |
| 49.1. Description.....                                 | 1449 |
| 49.2. Embedded Characteristics.....                    | 1449 |
| 49.3. Block Diagram.....                               | 1450 |
| 49.4. Pin List.....                                    | 1451 |
| 49.5. Product Dependencies.....                        | 1451 |
| 49.6. Functional Description.....                      | 1451 |
| 49.7. Register Summary.....                            | 1473 |
| 50. Pulse Width Modulation Controller (PWM).....       | 1505 |
| 50.1. Description.....                                 | 1505 |
| 50.2. Embedded Characteristics.....                    | 1505 |
| 50.3. Block Diagram.....                               | 1507 |
| 50.4. I/O Lines Description.....                       | 1507 |
| 50.5. Product Dependencies.....                        | 1508 |
| 50.6. Functional Description.....                      | 1509 |
| 50.7. Register Summary.....                            | 1549 |
| 51. Analog Front-End Controller (AFEC).....            | 1613 |
| 51.1. Description.....                                 | 1613 |
| 51.2. Embedded Characteristics.....                    | 1613 |
| 51.3. Block Diagram.....                               | 1614 |
| 51.4. Signal Description.....                          | 1614 |
| 51.5. Product Dependencies.....                        | 1615 |
| 51.6. Functional Description.....                      | 1615 |
| 51.7. Register Summary.....                            | 1631 |
| 52. Digital-to-Analog Converter Controller (DACC)..... | 1665 |
| 52.1. Description.....                                 | 1665 |
| 52.2. Embedded Characteristics.....                    | 1665 |
| 52.3. Block Diagram.....                               | 1666 |
| 52.4. Signal Description.....                          | 1666 |
| 52.5. Product Dependencies.....                        | 1667 |
| 52.6. Functional Description.....                      | 1667 |
| 52.7. Register Summary.....                            | 1673 |
| 53. Analog Comparator Controller (ACC).....            | 1689 |
| 53.1. Description.....                                 | 1689 |
| 53.2. Embedded Characteristics.....                    | 1689 |

|   |      |
|---|------|
| 53.3. Block Diagram.....                            | 1689 |
| 53.4. Signal Description.....                       | 1690 |
| 53.5. Product Dependencies.....                     | 1690 |
| 53.6. Functional Description.....                   | 1690 |
| 53.7. Register Summary.....                         | 1692 |
| 54. Integrity Check Monitor (ICM).....              | 1703 |
| 54.1. Description.....                              | 1703 |
| 54.2. Embedded Characteristics.....                 | 1704 |
| 54.3. Block Diagram.....                            | 1704 |
| 54.4. Product Dependencies.....                     | 1705 |
| 54.5. Functional Description.....                   | 1705 |
| 54.6. Register Summary.....                         | 1718 |
| 55. True Random Number Generator (TRNG).....        | 1737 |
| 55.1. Description.....                              | 1737 |
| 55.2. Embedded Characteristics.....                 | 1737 |
| 55.3. Block Diagram.....                            | 1737 |
| 55.4. Product Dependencies.....                     | 1737 |
| 55.5. Functional Description.....                   | 1738 |
| 55.6. Register Summary.....                         | 1739 |
| 56. Advanced Encryption Standard (AES).....         | 1746 |
| 56.1. Description.....                              | 1746 |
| 56.2. Embedded Characteristics.....                 | 1746 |
| 56.3. Product Dependencies.....                     | 1746 |
| 56.4. Functional Description.....                   | 1747 |
| 56.5. Register Summary.....                         | 1758 |
| 57. Electrical Characteristics for SAM V70/V71..... | 1778 |
| 57.1. Absolute Maximum Ratings.....                 | 1778 |
| 57.2. DC Characteristics.....                       | 1779 |

# SAM E70/S70/V70/V71

## Configuration Summary

### 1. Configuration Summary

The SAM E70/S70/V70/V71 devices differ in memory size, package and features. The following tables summarize the different configurations.

**Table 1-1. SAM V71 Family Features (With CAN-FD, Ethernet AVB and Media LB)**

| Device      | Flash Memory (KB) | Multi-port SRAM Memory (KB) | Pins | Packages    | Digital Peripherals |            |          |           |        |                 |        |              |          |                              |      |      |                              |              |     |     |                        | Analog                     |      |          |                     |                    |                |
|-------------|-------------------|-----------------------------|------|-------------|---------------------|------------|----------|-----------|--------|-----------------|--------|--------------|----------|------------------------------|------|------|------------------------------|--------------|-----|-----|------------------------|----------------------------|------|----------|---------------------|--------------------|----------------|
|             |                   |                             |      |             | USB (see Note)      | USART/UART | QSPI     | USART/SPI | TWI/HS | HSMCI port/bits | CAN-FD | Ethernet AVB | Media LB | Image Sensor Interface (ISI) | SPI0 | SPI1 | External Bus Interface (EBI) | DMA Channels | SSC | ETM | Timer Counter Channels | Timer Counter Channels I/O | I2SC | I/O Pins | 12-bit ADC Channels | Analog Comparators | DAC (Channels) |
| ATSAMV71Q19 | 512               | 256                         | 144  | LQFP, TFBGA | HS                  | 3/5        | Y        | 3         | 3      | 1/4             | 2      | MII, RMII    | Y        | 12-bit                       | Y    | Y    | Y                            | 24           | Y   | Y   | 12                     | 36                         | 2    | 114      | 24                  | Y                  | 2              |

**Note:** HS = High-Speed and FS = Full-Speed.

## 2. Ordering Information

**ATSAM V71 Q 21 B - ANB**

**Product Family**

SAM = SMART ARM Microcontroller

**Product Series**

V71 = Cortex-M7 + Advanced Feature Set  
+ Ethernet + up to 2 CAN-FD + Media LB  
V70 = Cortex-M7 + Advanced Feature Set  
+ up to 2 CAN-FD + Media LB  
E70 = Cortex-M7 + Advanced Feature Set  
+ Ethernet + up to 2 CAN-FD  
S70 = Cortex-M7 + Advanced Feature Set

**Pin Count**

J = 64 pins  
N = 100 pins  
Q = 144 pins

**Flash Memory Density**

21 = 2048 KB  
20 = 1024 KB  
19 = 512 KB

**Package Carrier (If Applicable)**

T = Tape and Reel

**Temperature Operating Range**

N = Industrial (-40 - +105°C)  
B = Grade 2 (-40 - +105°C)

**Package Type**

A = LQFP  
AA = LQFP (1)  
C = LFBGA/TFBGA  
CF = UFBGA/VFBGA  
M = QFN

**Device Variant**

A = Revision A, legacy version  
B = Revision B, current variant

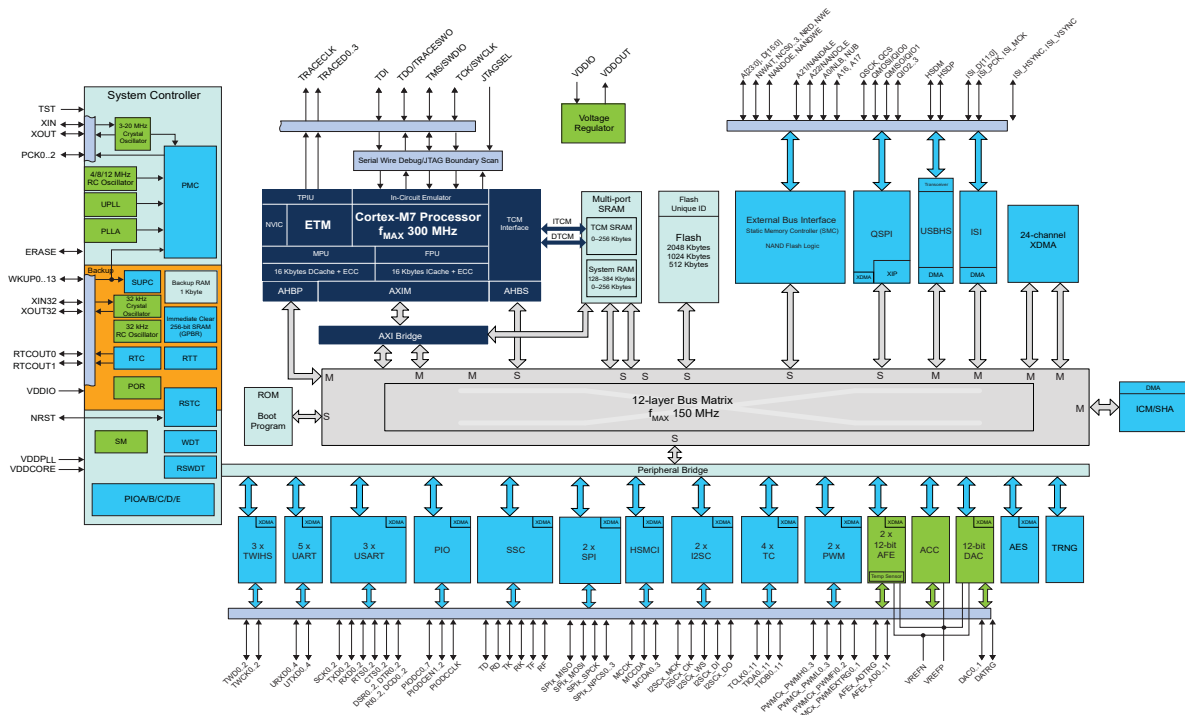

**Note:**

1. LQFP package type for Grade 2 variants.

### 3. Block Diagram

Refer to the table 1. Configuration Summary for detailed configurations of memory size, package and features of the SAM E70/S70/V70/V71 devices.

## 4. Signal Description

The following table provides details on signal names classified by peripherals.

**Table 4-1. Signal Description List**

| Signal Name                             | Function   | Type   | Active Level | Voltage Reference | Comments  |
|---|--|--------|--------------|-------------------|---|
| Power Supplies                          |  |        |              |                   |   |
| VDDIO                                   | Peripherals I/O Lines Power Supply   | Power  | –            | –                 | –   |
| VDDIN                                   | Voltage Regulator Input, AFE, DAC, and Analog Comparator Power Supply <sup>(1)</sup> | Power  | –            | –                 | –   |
| VDDOUT                                  | Voltage Regulator Output   | Power  | –            | –                 | –   |
| VDDPLL                                  | PLLA Power Supply  | Power  | –            | –                 | –   |
| VDDPLLUSB                               | USB PLL and Oscillator Power Supply  | Power  | –            | –                 | –   |
| VDDCORE                                 | Powers the core, the embedded memories and the peripherals                           | Power  | –            | –                 | –   |
| GND, GNDPLL, GNDPLLUSB, GNDANA, GNDUTMI | Ground   | Ground | –            | –                 | –   |
| VDDUTMII                                | USB Transceiver Power Supply   | Power  | –            | –                 | –   |
| VDDUTMIC                                | USB Core Power Supply  | Power  | –            | –                 | –   |
| GNDUTMI                                 | USB Ground   | Ground | –            | –                 | –   |
| Clocks, Oscillators, and PLLs           |  |        |              |                   |   |
| XIN                                     | Main Oscillator Input  | Input  | –            | VDDIO             | If any signal is not used, its PIO pin should be setup as an output, driven low, and attached to a dedicated trace on the board in order to reduce current consumption. |
| XOUT                                    | Main Oscillator Output   | Output | –            |                   |   |
| XIN32                                   | Slow Clock Oscillator Input  | Input  | –            |                   |   |
| XOUT32                                  | Slow Clock Oscillator Output   | Output | –            |                   |   |
| PCK0–PCK2                               | Programmable Clock Output  | Output | –            |                   |   |
| Real Time Clock                         |  |        |              |                   |   |
| RTCOUT0                                 | Programmable RTC Waveform Output   | Output | –            | VDDIO             | –   |
| RTCOUT1                                 | Programmable RTC Waveform Output   | Output | –            |                   | –   |

**Notes:**

1. Refer to the [Active Mode](#) section in the *Power Considerations* chapter for restrictions on the voltage range of analog cells.
2. AFE0\_AD11 is not an actual pin but is connected to a temperature sensor.

## 5. Automotive Quality Grade

The SAM V70 and SAM V71 devices are developed and manufactured according to the most stringent requirements of the international standard ISO-TS-16949. This data sheet contains limited values extracted from the results of extensive characterization (temperature and voltage).

The quality and reliability of the SAM V70 and SAM V71 has been verified during regular product qualification as per AEC-Q100 grade 2 (–40°C to +105°C).

**Table 5-1. Temperature Grade Identification for Automotive Products**

| Temperature (°C) | Temperature Identifier | Comments         |
|------------------|------------------------|------------------|
| –40°C to +105°C  | B                      | AEC-Q100 Grade 2 |

## 6. Package and Pinout

In the tables that follow, the column “Reset State” indicates the reset state of the line with mnemonics.

- “PIO” / “I” signal

Indicates whether the PIO Line resets in I/O mode or in peripheral mode. If “PIO” is mentioned, the PIO line is maintained in a static state as soon as the reset is released. As a result, the bit corresponding to the PIO line in the register PIO\_PSR (Peripheral Status Register) resets low.

If a signal name is mentioned in the “Reset State” column, the PIO line is assigned to this function and the corresponding bit in PIO\_PSR resets high. This is the case of pins controlling memories, in particular the address lines, which require the pin to be driven as soon as the reset is released.

- “I” / “O”

Indicates whether the signal is input or output state.

- “PU” / “PD”

Indicates whether pullup, pulldown, or nothing is enabled.

- “ST”

Indicates if Schmitt Trigger is enabled.

### Notes:

1. WKUPx can be used if the PIO Controller defines the I/O line as "input".
2. To select this extra function, refer to the [32.5.14. Parallel Capture Mode](#) section in the Parallel Input/Output Controller (PIO) chapter.
3. PIODCEN1/PIODCx has priority over WKUPx. Refer to the [32.5.14. Parallel Capture Mode](#) section in the PIO chapter.
4. Refer to the [23.4.2. Slow Clock Generator](#) section in the Supply Controller (SUPC) chapter.
5. To select this extra function, refer to the [33.5.2.1. I/O Lines](#) section in the External Bus Interface (EBI) chapter. This selection is independent of the PIO line configuration. PIO lines must be configured according to required settings (PU or PD).
6. Analog input has priority over WKUPx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the EBI chapter. WKUPx can be used if the PIO controller defines the I/O line as "input".
7. Analog input has priority over RTCOUTx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the EBI chapter. Refer to the [27.5.8. Waveform Generation](#) section in the Real-Time Clock (RTC) chapter to select RTCOUTx.
8. Analog input has priority over WKUPx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the EBI chapter. To select PIODCEN2, refer to the [32.5.14. Parallel Capture Mode](#) in the PIO chapter.
9. Refer to the System I/O Configuration Register ([19.4.7. CCFG\\_SYSIO](#)) in the Bus Matrix (MATRIX) chapter.
10. Refer to the [30.5.3. Main Crystal Oscillator](#) section in the Clock Generator chapter. This selection is independent of the PIO line configuration. PIO lines must be configured according to XINxx (I) and XOUTxx (O).
11. DAC0 is selected when DACC\_CHER.CH0 is set. DAC1 is selected when DACC\_CHER.CH1 is set. Refer to the [DACC Channel Enable Register](#) in the Digital-to-Analog Converter Controller (DACC) chapter.

### 6.3 100-lead Packages

#### 6.3.1 100-pin LQFP Package Outline

Figure 6-4. Orientation of the 100-lead LQFP Package

#### 6.3.2 100-ball TFBGA Package Outline

The 100-ball TFBGA package has a 0.8 mm ball pitch and respects Green standards. Its dimensions are 9 x 9 x 1.1 mm. The figure below shows the orientation of the 100-ball TFBGA Package.

Figure 6-5. Orientation of the 100-ball TFBGA Package

#### 6.3.3 100-ball VFBGA Package Outline

100-ball VFBGA Package Outline

The 100-ball VFBGA package has a 0.65 mm ball pitch and respects Green standards. The dimensions are 7mm x 7mm x 1.0 mm.

The following figure shows the orientation of the 100-ball VFBGA Package.

Figure 6-6. 100-ball VFBGA Package Outline

### Notes:

1. WKUPx can be used if the PIO Controller defines the I/O line as “input”.
2. To select this extra function, refer to the [32.5.14. Parallel Capture Mode](#) section in the “Parallel Input/Output Controller (PIO)” chapter.
3. PIODCEN1/PIODCx has priority over WKUPx. Refer to the [32.5.14. Parallel Capture Mode](#) section in the “PIO” chapter.
4. Refer to the [23.4.2. Slow Clock Generator](#) section in the “Supply Controller (SUPC)” chapter.
5. To select this extra function, refer to the [33.5.2.1. I/O Lines](#) section in the “External Bus Interface (EBI)” chapter. This selection is independent of the PIO line configuration. PIO lines must be configured according to required settings (PU or PD).
6. Analog input has priority over WKUPx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the “EBI” chapter. WKUPx can be used if the PIO controller defines the I/O line as “input”.
7. Analog input has priority over RTCOUTx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the “EBI” chapter. Refer to the [27.5.8. Waveform Generation](#) section in the “Real-Time Clock (RTC)” chapter to select RTCOUTx.
8. Analog input has priority over WKUPx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the “EBI” chapter. To select PIODCEN2, refer to the [32.5.14. Parallel Capture Mode](#) in the “PIO” chapter.
9. Refer to the System I/O Configuration Register ([19.4.7. CCFG\\_SYSIO](#)) in the “Bus Matrix (MATRIX)” chapter.
10. Refer to the [30.5.3. Main Crystal Oscillator](#) section in the “Clock Generator” chapter. This selection is independent of the PIO line configuration. PIO lines must be configured according to XINxx (I) and XOUTxx (O).
11. DAC0 is selected when DACC\_CHER.CH0 is set. DAC1 is selected when DACC\_CHER.CH1 is set. Refer to the [DACC Channel Enable Register](#) in the “Digital-to-Analog Converter Controller (DACC)” chapter.

**Notes:**

1. To select this extra function, refer to the [32.5.14. Parallel Capture Mode](#) section in the “Parallel Input/Output Controller (PIO)” chapter.
2. PIODCEN1/PIODCx has priority over WKUPx. Refer to the [32.5.14. Parallel Capture Mode](#) section in the “PIO” chapter.
3. Refer to the [23.4.2. Slow Clock Generator](#) section in the “Supply Controller (SUPC)” chapter.
4. To select this extra function, refer to the [33.5.2.1. I/O Lines](#) section in the “External Bus Interface (EBI)” chapter. This selection is independent of the PIO line configuration. PIO lines must be configured according to required settings (PU or PD).
5. Analog input has priority over WKUPx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the “EBI” chapter. WKUPx can be used if the PIO controller defines the I/O line as “input”.
6. Analog input has priority over RTCOUTx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the “EBI” chapter. Refer to the [27.5.8. Waveform Generation](#) section in the “Real-Time Clock (RTC)” chapter to select RTCOUTx.
7. Analog input has priority over WKUPx pin. To select the analog input, refer to the [33.5.2.1. I/O Lines](#) section in the “EBI” chapter. To select PIODCEN2, refer to the [32.5.14. Parallel Capture Mode](#) in the “PIO” chapter.
8. Refer to the System I/O Configuration Register ([19.4.7. CCFG\\_SYSIO](#)) in the “Bus Matrix (MATRIX)” chapter.
9. Refer to the [30.5.3. Main Crystal Oscillator](#) section in the Clock Generator chapter. This selection is independent of the PIO line configuration. PIO lines must be configured according to XINxx (I) and XOUTxx (O).
10. DAC0 is selected when DACC\_CHER.CH0 is set. DAC1 is selected when DACC\_CHER.CH1 is set. Refer to the [DAC Channel Enable Register](#) in the “Digital-to-Analog Converter Controller (DACC)” chapter.
11. The exposed pad of the QFN64 package MUST be connected to ground.

**Note:** Pinout limitations prevent full support of USART functionality. The following table lists which USART functions are available.

**Table 6-4. USART Functions**

| USART Pins |                         |          | Availability |        |
|------------|-------------------------|----------|--------------|--------|
| Function   | Description             | Pin Name | USART0       | USART1 |
| SCK        | Serial Clock            | SCK      | n            | n      |
| TXD        | Transmit Data           | UTXDx    | y            | y      |
| RXD        | Receive Data            | URXDx    | y            | y      |
| RTS        | Request to Send         | RTSx     | y            | y      |
| CTS        | Clear To Send           | CTSx     | y            | n      |
| DTR        | Data Terminal Ready     | DTRx     | y            | y      |
| DSR        | Data Set Ready          | DSRx     | y            | n      |
| DCD        | Data Carrier Detect     | DCDx     | y            | n      |
| RI         | Ring Indicator          | RIx      | y            | n      |
| LCOL       | LON Collision Detection | LONCOLx  | n            | y      |

## 7. Power Considerations

### 7.1 Power Supplies

The following table defines the power supply rails of the SAM E70/S70/V70/V71 .

**Table 7-1. Power Supplies**

| Name      | Associated Ground | Powers  |
|-----------|-------------------|---|
| VDDCORE   | GND               | Core, embedded memories and peripherals.  |
| VDDIO     | GND               | Peripheral I/O lines (Input/Output Buffers), backup part, 1 Kbytes of backup SRAM, 32 kHz crystal oscillator, oscillator pads. For USB operations, VDDIO voltage range must be between 3.0V and 3.6V. |
| VDDIN     | GND, GNDANA       | Voltage regulator input. Supplies also the ADC, DAC, and analog voltage comparator.   |
| VDDPLL    | GND, GNDPLL       | PLLA and the fast RC oscillator.  |
| VDDPLLUSB | GND, GNDPLLUSB    | UTMI PLL and 3 MHz to 20 MHz oscillator.  |
| VDDUTMII  | GNDUTMI           | USB transceiver interface. Must be connected to VDDIO.  |
| VDDUTMIC  | GNDUTMI           | USB transceiver core.   |

### 7.2 Power Constraints

The following power constraints are apply to SAM E70/S70/V70/V71 devices. Deviating from these constraints may lead to unpredictable results.

- VDDIN and VDDIO must have the same level
- VDDIN and VDDIO must always be higher than or equal to VDDCORE
- VDDCORE, VDDPLL and VDDUTMIC voltage levels must not vary by more than 0.6V
- For the USB to be operational, VDDUTMII, VDDPLLUSB, VDDIN and VDDIO must be higher than or equal to 3.0V

#### 7.2.1 Powerup

VDDIO and VDDIN must rise simultaneously, prior to VDDCORE, VDDPLL and VDDUTMIC rising. This is respected if VDDCORE, VDDPLL and VDDUTMIC are supplied by the embedded voltage regulator.

If VDDCORE is powered by an external voltage regulator, VDDIO and VDDIN must reach their minimum operating voltage before VDDCORE has reached  $V_{DDCORE_{min}}$ . The minimum slope for VDDCORE is defined by:

$$(V_{DDCORE_{min}} - V_{T+min}) / (t_{RESmin})$$

If VDDCORE rises at the same time as VDDIO and VDDIN, the minimum and maximum rising slopes of VDDIO and VDDIN must be respected. Refer to the section “DC Characteristics”.

In order to prevent any overcurrent at powerup, it is required that VREFP rises simultaneously with VDDIO and VDDIN.

**Figure 7-1. Powerup Sequence**

**Related Links**

- [57.2. DC Characteristics](#)
- [23.4.6. Backup Power Supply Reset](#)
- [23.4.6.1. Raising the Backup Power Supply](#)

**7.2.2 Powerdown**

If VDDCORE, VDDPLL and VDDUTMIC are not supplied by the embedded voltage regulator, VDDIO, VDDIN, VDDPLLUSB and VDDUTMII should fall simultaneously, prior to VDDCORE, VDDPLL and VDDUTMIC falling. The VDDCORE falling slope must not be faster than 20V/ms.

In order to prevent any overcurrent at powerdown, it is required that VREFP falls simultaneously with VDDIO and VDDIN.

**Figure 7-2. Powerdown Sequence**

**7.3 Voltage Regulator**

The SAM E70/S70/V70/V71 embeds a voltage regulator that is managed by the Supply Controller.

For adequate input and output power supply decoupling/bypassing, refer to [57.2. DC Characteristics](#) in the Electrical Characteristics chapter.

**7.4 Backup SRAM Power Switch**

The SAM E70/S70/V70/V71 embeds a power switch to supply the 1 Kbyte of backup SRAM. It is activated only when VDDCORE is switched off to ensure retention of the contents of the backup SRAM. When VDDCORE is switched on, the backup SRAM is powered with VDDCORE.

To save the power consumption of the backup SRAM, the user can disable the backup SRAM power switch by clearing the bit SRAMON in the Supply Controller Mode Register (SUPC\_MR). By default, after VDDIO rises, the backup SRAM power switch is enabled.

## 7.5 Active Mode

Active mode is the normal running mode with the core clock running from the fast RC oscillator, the main crystal oscillator or the PLLA. The Power Management Controller can be used to adapt the core, bus and peripheral frequencies and to enable and/or disable the peripheral clocks.

## 7.6 Low-power Modes

The SAM E70/S70/V70/V71 features the following three Low-Power modes:

- Backup mode
- Wait mode
- Sleep mode

### 7.6.1 Backup Mode

The purpose of Backup mode is to achieve the lowest power consumption possible in a system which is performing periodic wakeups to perform tasks but not requiring fast startup time.

The Supply Controller, zero-power Power-On Reset (POR), RTT, RTC, backup SRAM, backup registers and 32 kHz oscillator (RC or crystal oscillator selected by software in the Supply Controller) are running. The regulator and the core supply are off.

Backup mode is based on the Cortex-M7 Deep-Sleep mode with the voltage regulator disabled.

Wakeup from Backup mode is done through WKUP0–13 pins, the supply monitor (SM), the RTT, or an RTC wakeup event.

Backup mode is entered by using the VROFFbit in the Supply Controller Control Register (SUPC\_CR) and the SLEEPDEEP bit in the Cortex-M7 System Control Register set to 1. Refer to information on Power Management in the "ARM Cortex-M7 documentation", which is available for download at [www.arm.com](http://www.arm.com).

To enter Backup mode, follow these steps:

1. Set the SLEEPDEEP bit of the Cortex-M7 processor.
2. Set the VROFF bit of SUPC\_CR.

Exit from Backup mode occurs as a result of one of the following enabled wakeup events:

- WKUP0–13 pins (level transition, configurable debouncing)
- Supply Monitor alarm
- RTC alarm
- RTT alarm

**Notes:** If PLLA is enabled with the Main Crystal Oscillator as the clock source for Main Clock (MAINCK), the following sequence must be followed before entering into backup mode:

1. Switch Main Clock (MAINCK) to Slow Clock (SLCK) by using PMC\_MCKR.CSS.
2. Disable the PLLA by writing MUL = 0 or DIV = 0.
3. Disable the Main Crystal Oscillator.
4. Add Wait time in the range of milliseconds.
5. Enter backup mode.

### 7.6.2 Wait Mode

The purpose of Wait mode is to achieve very low-power consumption while maintaining the whole device in a powered state for a startup time of less than 10  $\mu$ s.

In Wait mode, the clocks of the core, peripherals and memories are stopped. However, the core, peripherals and memories power supplies are still powered.

Wait mode is entered when the WAITMODE bit is set in CKGR\_MOR and the field FLPM is configured to 00 or 01 in the PMC Fast Startup Mode register (PMC\_FSMR).

The Cortex-M is able to handle external events or internal events to wake up the core. This is done by configuring the external lines WKUP0–13 as fast startup wake-up pins (refer to the “Fast Startup” section). RTC or RTT alarms or USB wake-up events can be used to wake up the processor. Resume from Wait mode is also achieved when a debug request occurs and the bit CDBGPWRUPREQ is set in the processor.

To enter Wait mode, first, select the Main RC oscillator as Main Clock and perform the following steps:

1. Configure the FLPM field in the PMC\_FSMR.
2. Set Flash Wait State at 0.
3. Set HCLK = MCK by configuring MDIV to 0 in the PMC Host Clock register (PMC\_MCKR).
4. Set the WAITMODE bit in the PMC Clock Generator Main Oscillator register (CKGR\_MOR).
5. Wait for MCKRDY = 1 in the PMC Status register (PMC\_SR).

**Note:** Internal main clock resynchronization cycles are necessary between writing the MOSCRREN bit and the entry in Wait mode. Depending on the user application, waiting for the MOSCRREN bit to be cleared is recommended to ensure that the core will not execute undesired instructions.

### 7.6.3 Sleep Mode

The purpose of Sleep mode is to optimize power consumption of the device versus response time. In this mode, only the core clock is stopped. The peripheral clocks can be enabled. The current consumption in this mode is application-dependent.

This mode is entered using the instruction Wait for Interrupt (WFI).

Processor wakeup is triggered by an interrupt if the WFI instruction of the Cortex-M processor is used.

### 7.6.4 Low-Power Mode Summary Table

The modes detailed above are the main low-power modes. Each part can be set to on or off separately and wake up sources can be individually configured. The following table provides a summary of the configurations of the low-power modes.

**Table 7-2. Low-power Mode Configuration Summary**

| Mode                                       | SUPC, 32 kHz Oscillator, RTC, RTT Backup SRAM (BRAM), Backup Registers (GPBR), POR (Backup Area) | Regulator | Core Memory Peripherals | Mode Entry Configuration  | Potential Wakeup Sources   | Core at Wakeup            | PIO State while in Low-Power Mode | PIO State at Wakeup                               | Wakeup Time (see Note 2) |
|--|--|-----------|-------------------------|---|--|---------------------------|-----------------------------------|---|--------------------------|
| Backup Mode                                | ON   | OFF       | OFF (Not powered)       | SUPC_CR.VROFF = 1<br>SLEEPDEEP = 1 (see Note 1)   | WKUP0–13 pins<br>Supply Monitor<br>RTC alarm<br>RTT alarm  | Reset                     | Previous state maintained         | PIOA, PIOB, PIOC, PIOD & PIOE inputs with pullups | < 2 ms                   |
| Wait Mode w/ Flash in Deep Power-down Mode | ON   | ON        | Powered (Not clocked)   | PMC_MCKR.MDIV = 0<br>, CKGR_MOR.WAITMODE = 1<br>, SLEEPDEEP = 0<br>, PMC_FSMR.LPM = 1<br>, PMC_FSMR.FLPM = 1 (see Note 1) | WKUP0–13 pins<br>RTC<br>RTT<br>USBHS<br>Processor debug (see Note 6)<br>GMAC Wake on LAN event<br>Wakeup from CAN (see Note 7) | Clocked back (see Note 3) | Previous state maintained         | Unchanged   | < 10 μs                  |

# SAM E70/S70/V70/V71

## Power Considerations

### Notes:

1. The bit SLEEPDEEP is in the Cortex-M7 System Control Register.
2. When considering wakeup time, the time required to start the PLL is not taken into account. Once started, the device works with the Main RC oscillator. The user has to add the PLL startup time if it is needed in the system. The wakeup time is defined as the time taken for wakeup until the first instruction is fetched.
3. HCLK = MCK. The user may need to revert back to the previous clock configuration.
4. Depends on MCK frequency.
5. In this mode, the core is supplied and not clocked. Some peripherals can be clocked.
6. Resume from Wait mode if a debug request occurs (CDBGPWRUPREQ is set in the processor).
7. CAN wake-up requires the use of any WKUP0–13 pin.

## 7.7 Wakeup Sources

Wakeup events allow the device to exit Backup mode. When a wakeup event is detected, the Supply Controller performs a sequence which automatically reenables the core power supply and the SRAM power supply, if they are not already enabled.

## 7.8 Fast Startup

The SAM E70/S70/V70/V71 allows the processor to restart in a few microseconds while the processor is in Wait mode or in Sleep mode. A fast startup can occur upon detection of a low level on any of the following wake-up sources:

- WKUP0 to WKUP13 pins
- Supply Monitor
- RTC alarm
- RTT alarm
- USBHS interrupt line (WAKEUP)
- Processor debug request (CDBGPWRUPREQ)
- GMAC wake on LAN event

**Note:** CAN wake-up requires the use of any WKUP0–13 pin.

The fast restart circuitry is fully asynchronous and provides a fast startup signal to the Power Management Controller. As soon as the fast startup signal is asserted, the PMC automatically restarts the Main RC oscillator, switches the Host clock on this clock and re-enables the processor clock.

## 8. Input/Output Lines

The SAM E70/S70/V70/V71 features both general purpose I/Os (GPIO) and system I/Os. GPIOs can have alternate functionality due to multiplexing capabilities of the PIO controllers. The same PIO line can be used, whether in I/O mode or by the multiplexed peripherals. System I/Os include pins such as test pins, oscillators, erase or analog inputs.

### 8.1 General-Purpose I/O Lines

General-purpose I/O (GPIO) lines are managed by PIO Controllers. All I/Os have several input or output modes, such as pull up or pull down, input Schmitt triggers, multi-drive (open-drain), glitch filters, debouncing or input change interrupt. Programming of these modes is performed independently for each I/O line through the PIO controller user interface. For additional information, refer to the [32. Parallel Input/Output Controller \(PIO\)](#).

The input/output buffers of the PIO lines are supplied through VDDIO power supply rail.

The SAM E70/S70/V70/V71 devices embed high-speed pads capable of handling high-speed clocks for HSMCI, SPI and QSPI (MCK/2). Refer to the [57. Electrical Characteristics for SAM V70/V71](#) for additional information. Typical pull-up and pull-down value is 100 k $\Omega$  for all I/Os.

Each I/O line also embeds a  $R_{SERIAL}$  (On-die Serial Resistor), as shown in the following figure. It consists of an internal series resistor termination scheme for impedance matching between the driver output (SAM E70/S70/V70/V71) and the PCB trace impedance preventing signal reflection. The series resistor helps to reduce I/Os switching current (di/dt), thereby reducing in turn, EMI. It also decreases overshoot and undershoot (ringing) due to inductance of interconnect between devices or between boards. Finally,  $R_{SERIAL}$  helps diminish signal integrity issues. The following figure illustrates the On-Die Termination (ODT).

**Note:** Refer to the [DC Characteristics tables](#) in the [Electrical Characteristics](#) chapter.

**Figure 8-1. On-Die Termination**

### 8.2 System I/O Lines

System I/O lines are pins used by oscillators, Test mode, reset, JTAG and other features. The following table lists the SAM E70/S70/V70/V71 system I/O lines shared with PIO lines.

These pins are software-configurable as general-purpose I/Os or system pins. At startup, the default function of these pins is always used.

**Table 8-1. System I/O Configuration Pin List**

| CCFG_SYSIO Bit Number | Default Function After Reset | Other Function | Constraints for Normal Start              | Configuration  |
|-----------------------|------------------------------|----------------|---|--|
| 12                    | ERASE                        | PB12           | Low Level at startup (see <b>Note 1</b> ) | In Matrix User Interface Registers (Refer to the <a href="#">19.4.7. CCFG_SYSIO register</a> ) |
| 7                     | TCK/SWCLK                    | PB7            | –   |  |
| 6                     | TMS/SWDIO                    | PB6            | –   |  |
| 5                     | TDO/TRACESWO                 | PB5            | –   |  |
| 4                     | TDI                          | PB4            | –   |  |
| –                     | PA7                          | XIN32          | –   | (see <b>Note 2 and 4</b> )   |
| –                     | PA8                          | XOUT32         | –   |  |
| –                     | PB9                          | XIN            | –   | (see <b>Note 3 and 4</b> )   |
| –                     | PB8                          | XOUT           | –   |  |

**Notes:**

1. If the PB12 pin is used as PIO input in user applications, a low level must be ensured at start up to prevent Flash erase before the user application sets the PB12 pin into PIO mode.
2. Refer to [23.4.2. Slow Clock Generator](#).
3. Refer to [30.5.3. Main Crystal Oscillator](#).
4. If not used then the corresponding PIO pin must be setup as an output and attached to a dedicated trace on the board to reduce current consumption.

### 8.2.1 Serial Wire Debug Port (SW-DP) Pins

The SW-DP pins, SWCLK and SWDIO, are commonly provided on a standard 20-pin JTAG connector defined by ARM. For additional information about voltage reference and reset state, refer to the [Table 4-1](#).

At startup, the SW-DP pins are configured in SW-DP mode to allow connection with debugging probe. For more details, refer to [16. Debug and Test Features](#).

The SW-DP pins can be used as standard I/Os to provide users more general input/output pins when the debug port is not needed in the end application. Mode selection between SW-DP mode (System IO mode) and general IO mode is performed through the AHB Matrix Special Function Registers (MATRIX\_SFR). Configuration of the pad for pull-up, triggers, debouncing and glitch filters is possible regardless of the mode.

The JTAGSEL pin is used to select the JTAG boundary scan when asserted at a high level. It integrates a permanent pulldown resistor of about 15 kΩ to GND, so that it can be left unconnected for normal operations.

The JTAG Debug Port TDI, TDO, TMS and TCK is inactive. It is provided for Boundary Scan Manufacturing Test purpose only.

### 8.2.2 Embedded Trace Module (ETM) Pins

The Embedded Trace Module (ETM) depends on the Trace Port Interface Unit (TPIU) to export data out of the system.

The TPUI features the following pins:

- TRACECLK is always exported to enable synchronization with the data.
- TRACED0–TRACED3 is the instruction trace stream.

### 8.3 NRST Pin

The NRST pin is bidirectional. It is handled by the on-chip Reset Controller (RSTC) and can be driven low to provide a reset signal to the external components or asserted low externally to reset the microcontroller. It resets the core and the peripherals, with the exception of the Backup area (RTC, RTT, Backup SRAM and Supply Controller). The NRST pin integrates a permanent pullup resistor to VDDIO of about 100 k $\Omega$ .

By default, the pin is configured as an input.

### 8.4 ERASE Pin

The ERASE pin is used to perform hardware erase of the on-chip Flash and the NVM bits including GPNVM bits, Lock bits and the Security Bit. The hardware erase sequence will first erase the entire Flash and afterwards the NVM bits in order to fully secure the content of the on-chip Flash. The ERASE pin integrates a pull-down resistor of about 100 k $\Omega$  to GND, hence it can be left unconnected for normal operations.

The ERASE pin is a system I/O pin that can be used as a standard I/O. At startup, this system I/O pin defaults to the ERASE function. This pin is debounced by SLCK to improve the glitch tolerance. To avoid unexpected erase at power-up due to glitches, a minimum ERASE pin assertion time is required. This time is defined in [Table 57-49](#).

The erase operation cannot be performed when the system is in Wait mode.

If the ERASE pin is used as a standard I/O in Input or Output mode, note the following considerations and behavior:

- I/O Input mode: At startup of the device, the logic level of the pin must be low to prevent unwanted erasing until the user application has reconfigured this system I/O pin to a standard I/O pin.
- I/O Output mode: asserting the pin to low does not erase the Flash.

During software application development, a faulty software may put the device into a deadlock. This may be due to:

- Programming an incorrect clock switching sequence.
- Using this system I/O pin as a standard I/O pin.
- Entering Wait mode without any wakeup events programmed.

To recover normal behavior is to erase the Flash by following these steps:

1. Apply a logic "1" level on the ERASE pin.
2. Apply a logic "0" level on the NRST pin.
3. Power down and then power up the device.
4. Maintain the ERASE pin to logic "1" level for at least the minimum assertion time after releasing the NRST pin to logic "1" level.

## 9. Interconnect

The system architecture is based on the ARM Cortex-M7 processor connected to the main AHB Bus Matrix, the embedded Flash, the multi-port SRAM and the ROM.

The 32-bit AHBP interface is a single 32-bit wide interface that accesses the peripherals connected on the main Bus Matrix. It is used only for data access. Instruction fetches are never performed on the AHBP interface. The bus, AHBP or AXIM, accessing the peripheral memory area [0x40000000 to 0x60000000] is selected in the AHBP control register.

The 32-bit AHBS interface provides system access to the ITCM, D1TCM, and D0TCM. It is connected on the main Bus Matrix and allows the XDMA to transfer from memory or peripherals to the instruction or data TCMs.

The 64-bit AXIM interface is a single 64-bit wide interface connected through two ports of the AXI Bridge to the main AHB Bus Matrix and to two ports of the multi-port SRAM. The AXIM interface allows:

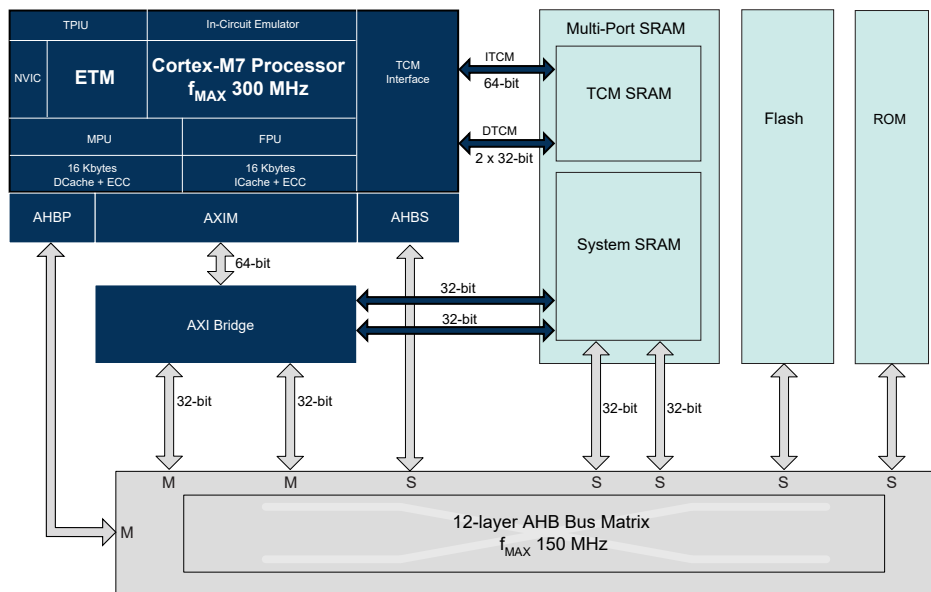

- Instruction fetches
- Data cache linefills and evictions
- Non-cacheable normal-type memory data accesses
- Device and strongly-ordered type data accesses, generally to peripherals

The interleaved multi-port SRAM optimizes the Cortex-M7 accesses to the internal SRAM.

The interconnect of the other Hosts and Clients is described in [19. Bus Matrix \(MATRIX\)](#).

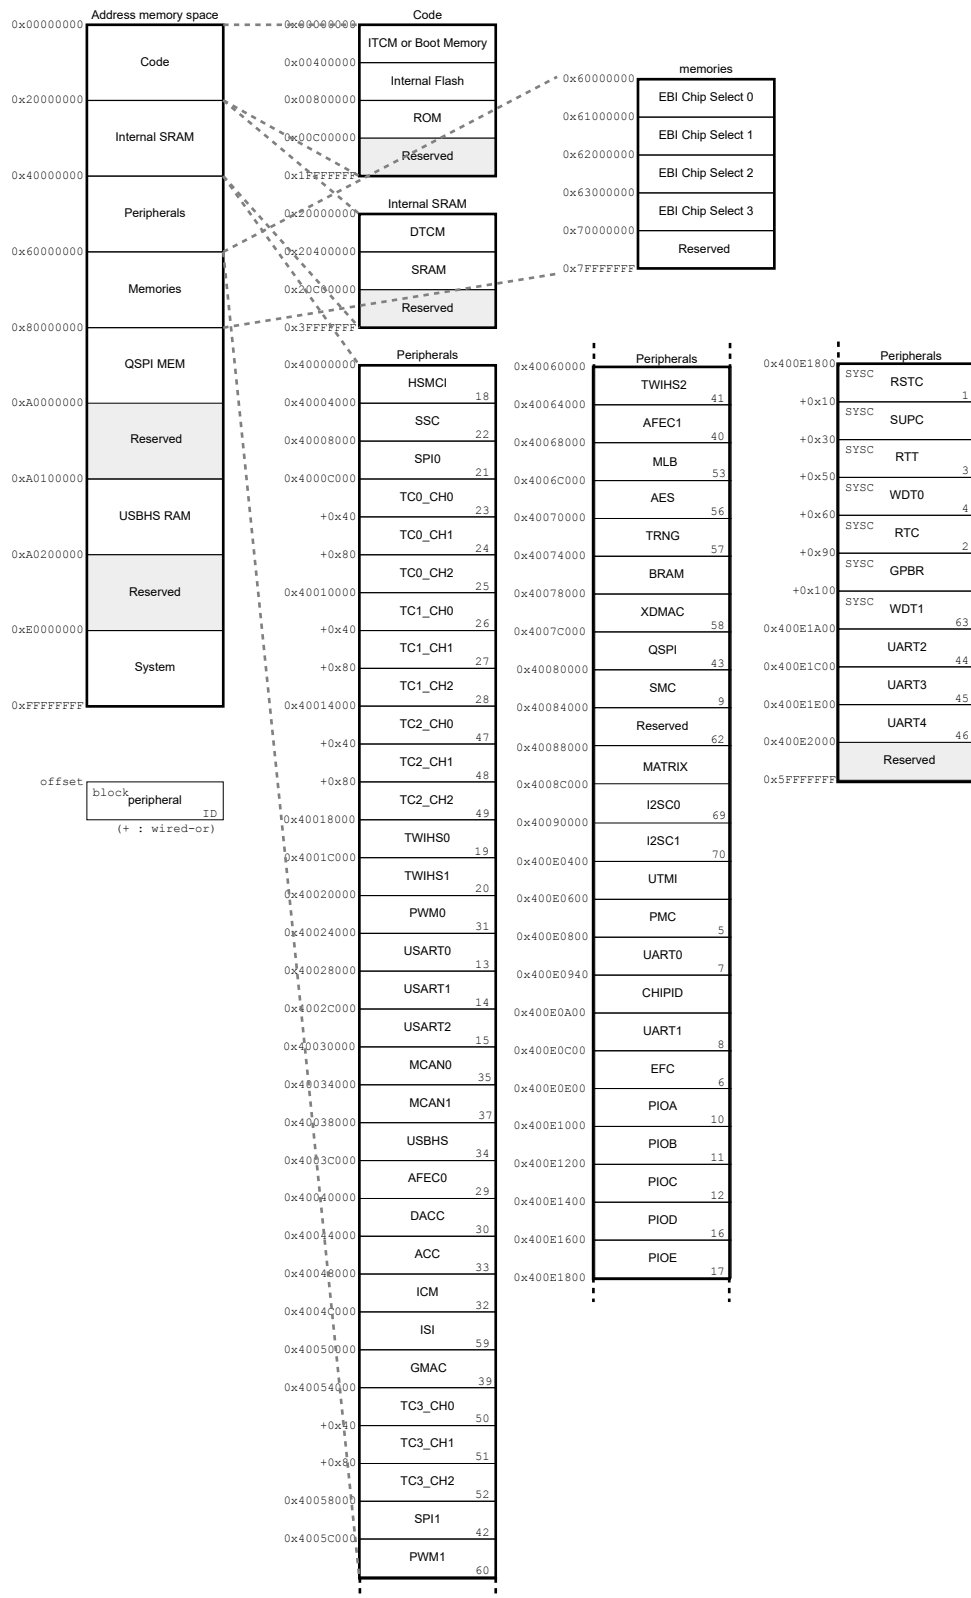

The figure below shows the connections of the different Cortex-M7 ports.

**Figure 9-1. Interconnect Block Diagram**

### 10. Product Mapping

Figure 10-1. SAM E70/S70/V70/V71 Product Mapping

## 11. Memories

### 11.1 Embedded Memories

#### 11.1.1 Internal SRAM

SAM E70/S70/V70/V71 devices embed 384 Kbytes or 256 Kbytes of high-speed SRAM.

The SRAM is accessible over the system Cortex-M bus at address 0x2040 0000.

SAM E70/S70/V70/V71 devices embed a Multi-Port SRAM with four ports to optimize the bandwidth and latency. The priorities, defined in the Bus Matrix for each SRAM port Client are propagated, for each request, up to the SRAM Clients.

The Bus Matrix supports four priority levels: Normal, Bandwidth-sensitive, Latency-sensitive and Latency-critical in order to increase the overall processor performance while securing the high-priority latency-critical requests from the peripherals.

The SRAM controller manages interleaved addressing of SRAM blocks to minimize access latencies. It uses Bus Matrix priorities to give the priority to the most urgent request. The less urgent request is performed no later than the next cycle.

Two SRAM Client ports are dedicated to the Cortex-M7 while two ports are shared by the AHB Hosts.

#### 11.1.2 Tightly Coupled Memory (TCM) Interface

SAM E70/S70/V70/V71 devices embed Tightly Coupled Memory (TCM) running at processor speed.

- ITCM is a single 64-bit interface, based at 0x0000 0000 (code region).
- DTCM is composed of dual 32-bit interfaces interleaved, based at 0x2000 0000 (data region).

ITCM and DTCM are enabled/disabled in the ITCMR and DTCMR registers in ARM SCB.

DTCM is enabled by default at reset. ITCM is disabled by default at reset.

There are four TCM configurations controlled by software. When enabled, ITCM is located at 0x0000 0000, overlapping ROM or Flash depending on the general-purpose NVM bit 1 (GPNVM). The configuration is done with GPNVM bits [8:7].

**Table 11-1. TCM Configurations in Kbytes**

| ITCM | DTCM | SRAM for 384K RAM-based | SRAM for 256K RAM-based | GPNVM Bits [8:7] |
|------|------|-------------------------|-------------------------|------------------|
| 0    | 0    | 384                     | 256                     | 0                |
| 32   | 32   | 320                     | 192                     | 1                |
| 64   | 64   | 256                     | 128                     | 2                |
| 128  | 128  | 128                     | 0                       | 3                |

Accesses made to TCM regions when the relevant TCM is disabled and accesses made to the Code and SRAM region above the TCM size limit are performed on the AHB matrix, i.e., on internal Flash or on ROM depending on remap GPNVM bit.

Accesses made to the SRAM above the size limit will not generate aborts.

The Memory Protection Unit (MPU) can be used to protect these areas.

#### 11.1.3 Internal ROM

The SAM E70/S70/V70/V71 embeds an Internal ROM for the SAM Boot Assistant (SAM-BA<sup>®</sup>), In Application Programming functions (IAP) and Fast Flash Programming Interface (FFPI).

At any time, the ROM is mapped at address 0x0080 0000.

The ROM may also be mapped at 0x00000000 depending on GPNVM bit setting and ITCM use.

### 11.1.4 Backup SRAM

The SAM E70/S70/V70/V71 embeds 1 Kbytes of backup SRAM located at 0x4007 4000.

The backup SRAM is accessible in 32-bit words only. Byte or half-word accesses are not supported.

The backup SRAM is supplied by VDDCORE in Normal mode.

In Backup mode, the backup SRAM supply is automatically switched to VDDIO through the backup SRAM power switch when VDDCORE falls. For more details, see the “[Backup SRAM Power Switch](#)” section.

### 11.1.5 Flash Memories

SAM E70/S70/V70/V71 devices embed 512 Kbytes, 1024 Kbytes, or 2084 Kbytes of internal Flash mapped at address 0x40 0000.

The devices feature a Quad SPI (QSPI) interface, mapped at address 0x80000000, that extends the Flash size by adding an external SPI or QSPI Flash.

When accessed by the Cortex-M7 processor for programming operations, the QSPI and internal Flash address spaces must be defined in the Cortex-M7 memory protection unit (MPU) with the attribute 'Device' or 'Strongly Ordered'. For fetch or read operations, the attribute 'Normal memory' must be set to benefit from the internal cache. For additional information, refer to the ARM Cortex-M7 Technical Reference Manual (ARM DDI 0489), which is available for download at [www.arm.com](http://www.arm.com).

Some precautions must be taken when the accesses are performed by the central DMA. Refer to the [22. Enhanced Embedded Flash Controller \(EEFC\)](#) and [41. Quad Serial Peripheral Interface \(QSPI\)](#).

#### 11.1.5.1 Embedded Flash Overview

The memory is organized in sectors and each sector has a size of 128 Kbytes. The first sector is divided into three smaller sectors which are organized in two sectors of 8 Kbytes and one sector of 112 Kbytes, see figure below.

**Figure 11-1. Global Flash Organization**

Each sector is organized in pages of 512 bytes.

For sector 0:

- The smaller sector 0 has 16 pages of 512 bytes
- The smaller sector 1 has 16 pages of 512 bytes
- The larger sector has 224 pages of 512 bytes

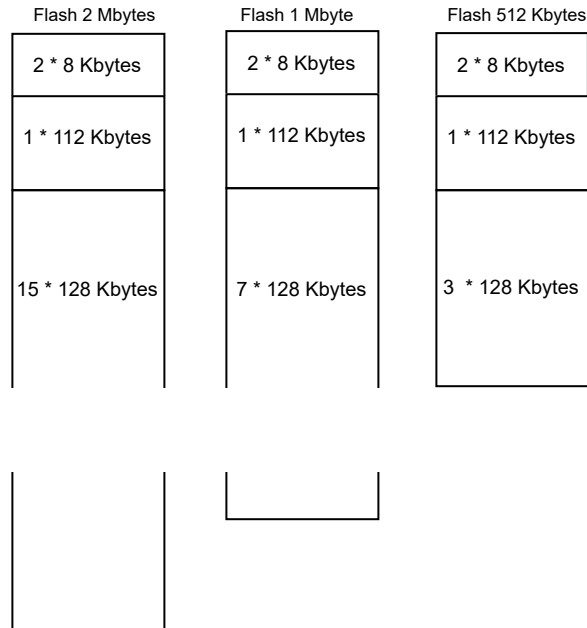

The rest of the array is composed of 128-Kbyte sectors of 256 pages of 512 bytes each, see image below.

**Figure 11-2. Flash Sector Organization**

The figure below illustrates the organization of the Flash depending on its size.

**Figure 11-3. Flash Size**

Erasing the memory can be performed:

- Chip Erase
- By block of 8 Kbytes
- By sector of 128 Kbytes
- By 512-byte page
  - Erase memory by page is possible only in an 8 Kbyte sector
  - EWP and EWPL commands can be only used in 8 Kbyte sectors

The memory has one additional reprogrammable page that can be used as page signature by the user. It is accessible through specific modes, for erase, write and read operations. Erase pin assertion will not erase the User Signature page.

### 11.1.5.2 Enhanced Embedded Flash Controller

Each Enhanced Embedded Flash Controller manages accesses performed by the hosts of the system. It enables reading the Flash and writing the write buffer. It also contains a User Interface, mapped on the APB.

The Enhanced Embedded Flash Controller ensures the interface of the Flash block.

It manages the programming, erasing, locking and unlocking sequences of the Flash using a full set of commands.

One of the commands returns the embedded Flash descriptor definition that informs the system about the Flash organization, thus making the software generic.

### 11.1.5.3 Flash Speed

The user must set the number of wait states depending on the system frequency.

For more details, refer to [Embedded Flash Characteristics](#).

### 11.1.5.4 Lock Regions

Several lock bits are used to protect write and erase operations on lock regions. A lock region is composed of several consecutive pages, and each lock region has its associated lock bit.

**Table 11-2. Flash Lock Bits**

| Flash Size (Kbytes) | Number of Lock Bits | Lock Region Size |
|---------------------|---------------------|------------------|
| 2048                | 128                 | 16 Kbytes        |

| .....continued      |                     |                  |
|---------------------|---------------------|------------------|
| Flash Size (Kbytes) | Number of Lock Bits | Lock Region Size |
| 1024                | 64                  | 16 Kbytes        |
| 512                 | 32                  | 16 Kbytes        |

Asserting the ERASE pin clears the lock bits, thus unlocking the entire Flash.

#### 11.1.5.5 Security Bit Feature

The SAM E70/S70/V70/V71 features a security bit based on the GPNVM bit 0. When security is enabled, any access to the Flash, SRAM, core registers and internal peripherals, either through the SW-DP, the ETM interface or the Fast Flash Programming Interface, is blocked. This ensures the confidentiality of the code programmed in the Flash.

This security bit can only be enabled through the command “Set General-purpose NVM Bit 0” of the EEFC User Interface. Disabling the security bit can only be achieved by asserting the ERASE pin at 1, and after a full Flash erase is performed. When the security bit is deactivated, all accesses to the Flash, SRAM, Core registers, Internal Peripherals are permitted.

#### 11.1.5.6 Unique Identifier

The device contains a unique identifier of 2 pages of 512 bytes. These 2 pages are read-only and cannot be erased even by the ERASE pin.

The sequence to read the unique identifier area is described in [22.4.3.8. Unique Identifier Area](#).

The mapping is as follows:

- Bytes [0..15]: 128 bits for unique identifier
- Bytes[16..1023]: Reserved

#### 11.1.5.7 User Signature

Each device contains a user signature of 512 bytes that is available to the user. The user signature can be used to store information such as trimming, keys, etc., that the user does not want to be erased by asserting the ERASE pin or by software ERASE command. Read, write and erase of this area is allowed.

#### 11.1.5.8 Fast Flash Programming Interface (FFPI)

The Fast Flash Programming Interface (FFPI) allows programming the device through a multiplexed fully-handshaked parallel port. It allows gang programming with market-standard industrial programmers.

The FFPI supports read, page program, page erase, full erase, lock, unlock and protect commands.

The FFPI is enabled and the Fast Programming mode is entered when TST and PA3 and PA4 are tied low.

**Table 11-3. FFPI on PIO Controller A (PIOA)**

| I/O Line | System Function |
|----------|-----------------|
| PD10     | PGMEN0          |
| PD11     | PGMEN1          |
| PB0      | PGMM0           |
| PB1      | PGMM1           |
| PB2      | PGMM2           |
| PB3      | PGMM3           |
| PA3      | PGMNCMD         |
| PA4      | PGMRDY          |
| PA5      | PGMNOE          |
| PA21     | PGMNVALID       |

.....continued

| I/O Line | System Function |
|----------|-----------------|
| PA7      | PGMD0           |
| PA8      | PGMD1           |
| PA9      | PGMD2           |
| PA10     | PGMD3           |
| PA11     | PGMD4           |
| PA12     | PGMD5           |
| PA13     | PGMD6           |
| PA14     | PGMD7           |
| PD0      | PGMD8           |
| PD1      | PGMD9           |
| PD2      | PGMD10          |
| PD3      | PGMD11          |
| PD4      | PGMD12          |
| PD5      | PGMD13          |
| PD6      | PGMD14          |
| PD7      | PGMD15          |

### 11.1.5.9 SAM-BA Boot

The SAM-BA Boot is a default boot program which provides an easy way to program in-situ the on-chip Flash memory.

The SAM-BA Boot Assistant supports serial communication via the UART0 and USB.

The SAM-BA Boot provides an interface with SAM-BA computer application.

The SAM-BA Boot is in ROM at address 0x0 when the bit GPNVM1 is set to 0.

### 11.1.5.10 General-purpose NVM (GPNVM) Bits

All SAM E70/S70/V70/V71 devices feature nine general-purpose NVM (GPNVM) bits that can be cleared or set, through the “Clear GPNVM Bit” and “Set GPNVM Bit” commands of the EEFC User Interface.

The GPNVM0 bit is the security bit.

The GPNVM1bit is used to select the Boot mode (Boot always at 0x00) on ROM or Flash.

**Table 11-4. General-purpose Non volatile Memory Bits**

| GPNVM Bit | Function  |
|-----------|---|
| 0         | Security bit  |
| 1         | Boot mode selection<br>0: ROM (default)<br>1: Flash |
| 5:2       | Free  |
| 6         | Reserved  |

.....continued

| GPNVM Bit | Function  |
|-----------|---|
| 8:7       | TCM configuration<br>00: 0 Kbytes DTCM + 0 Kbytes ITCM (default)<br>01: 32 Kbytes DTCM + 32 Kbytes ITCM<br>10: 64 Kbytes DTCM + 64 Kbytes ITCM<br>11: 128 Kbytes DTCM + 128 Kbytes ITCM<br><b>Note:</b> After programming, reboot must be done. |

### 11.1.6 Boot Strategies

The system always boots at address 0x0. To ensure maximum boot possibilities, the memory layout can be changed using GPNVM bits.

A GPNVM bit is used to boot either on the ROM (default) or from the Flash.

The GPNVM bit can be cleared or set, respectively, through the commands “Clear General-purpose NVM Bit” and “Set General-purpose NVM Bit” of the EEFC User Interface.

Setting the bit GPNVM1 selects boot from the Flash. Clearing it selects boot from the ROM. Asserting ERASE resets the bit GPNVM1 and thus selects boot from ROM.

## 11.2 External Memories

The SAM E70/S70/V70/V71 features one External Bus Interface to provide an interface to a wide range of external memories and to any parallel peripheral.

## 12. Event System

The events generated by peripherals (source) are designed to be directly routed to peripherals (destination) using these events without processor intervention. The trigger source can be programmed in the destination peripheral.

### 12.1 Embedded Characteristics

- Timers, PWM, I/Os and peripherals generate event triggers which are directly routed to destination peripherals, such as AFEC or DACC to start measurement/conversion without processor intervention.
- UART, USART, QSPI, SPI, TWI, PWM, HSMCI, AES, AFEC, DACC, PIO, TC (Capture mode) also generate event triggers directly connected to the DMA Controller for data transfer without processor intervention.
- Parallel capture logic is directly embedded in the PIO and generates trigger events to the DMA Controller to capture data without processor intervention.
- PWM safety events (faults) are in combinational form and directly routed from event generators (AFEC, ACC, PMC, TC) to the PWM module.
- PWM output comparators (OCx) generate events directly connected to the TC.
- PMC safety event (clock failure detection) can be programmed to switch the MCK on reliable main RC internal clock without processor intervention.

### 12.2 Real-time Event Mapping

**Table 12-1. Real-time Event Mapping List**

| Function | Application   | Description   | Event Source                        | Event Destination                              |
|----------|---|---|-------------------------------------|--|
| Safety   | General-purpose   | Automatic switch to reliable main RC oscillator in case of main crystal clock failure (see <b>Note 1</b> )        | Power Management Controller (PMC)   | PMC  |
|          | General-purpose, motor control, power factor correction (PFC) | Puts the PWM outputs in Safe mode in case of main crystal clock failure (see <b>Notes 1, 2</b> )                  | PMC                                 | Pulse Width Modulation 0 and 1 (PWM0 and PWM1) |
|          | Motor control, PFC  | Puts the PWM outputs in Safe mode (overcurrent detection, etc.) (see <b>Notes 2, 3</b> )                          | Analog Comparator Controller (ACC)  | PWM0 and PWM1                                  |
|          | Motor control, PFC  | Puts the PWM outputs in Safe mode (overspeed, overcurrent detection, etc.) (see <b>Notes 2, 4</b> )               | Analog Front-End Controller (AFEC0) | PWM0 and PWM1                                  |
|          |   |   | AFEC1                               | PWM0 and PWM1                                  |
|          | Motor control   | Puts the PWM outputs in Safe mode (overspeed detection through timer quadrature decoder) (see <b>Notes 2, 6</b> ) | TC0.Ch0                             | PWM0   |
|          |   |   | TC0.Ch1                             | PWM1   |
|          | General-purpose, motor control, power factor correction (PFC) | Puts the PWM outputs in Safe mode (general-purpose fault inputs) (see <b>Note 2</b> )                             | PIO PA9, PD8, PD9                   | PWM0   |
|          |   |   | PIO PA21, PA26, PA28                | PWM1   |

# SAM E70/S70/V70/V71

## 13. System Controller

The System Controller is a set of peripherals that handles key elements of the system, such as power, resets, clocks, time, interrupts, watchdog, and so on..

### 13.1 System Controller and Peripherals Mapping

Refer to the [“Product Mapping”](#) section.

### 13.2 Power-on-Reset, Brownout and Supply Monitor

The SAM E70/S70/V70/V71 embeds three features to monitor, warn and/or reset the chip:

- Power-on-Reset (POR) on VDDIO
- POR on VDDCORE
- Brown-out-Detector (BOD) on VDDCORE
- Supply Monitor on VDDIO

#### 13.2.1 Power-on-Reset

The Power-on-Reset (POR) monitors VDDIO and VDDCORE. It is always activated and monitors voltage at start up but also during power down. If VDDIO or VDDCORE goes below the threshold voltage, the entire chip is Reset. For more information, refer to [57. Electrical Characteristics for SAM V70/V71](#).

#### 13.2.2 Brownout Detector on VDDCORE

The Brown-out-Detector(BOD) monitors VDDCORE. It is active by default. It can be deactivated by software through the Supply Controller (SUPC\_MR). It is especially recommended to disable it during low-power modes, such as wait or sleep modes.

If VDDCORE goes below the threshold voltage, the reset of the core is asserted. For more information, refer to [23. Supply Controller \(SUPC\)](#) and [57. Electrical Characteristics for SAM V70/V71](#).

#### 13.2.3 Supply Monitor on VDDIO

The Supply Monitor monitors VDDIO. It is not active by default. It can be activated by software and is fully programmable with 16 steps for the threshold (between 1.6V to 3.4V). It is controlled by the Supply Controller (SUPC). A sample mode is possible, which allows the supply monitor power consumption to be divided by a factor of up to 2048. For more information, refer to [23. Supply Controller \(SUPC\)](#) and [57. Electrical Characteristics for SAM V70/V71](#).

## 13.3 Reset Controller

The Reset Controller is based on two POR cells, one on VDDIO and one on VDDCORE, and a Supply Monitor on VDDIO.

The Reset Controller returns the source of the last reset to the software. This may be a general reset, a wakeup reset, a software reset, a user reset or a watchdog reset.

The Reset Controller controls the internal resets of the system and the pin input/output. It can shape a reset signal for the external devices, simplifying the connection of a push-button on the NRST pin to implement a manual reset.

The configuration of the Reset Controller is saved as supplied on VDDIO.

## 14. Peripherals

### 14.1 Peripheral Identifiers

The following table defines the peripheral identifiers of the SAM E70/S70/V70/V71 devices. A peripheral identifier is required for the control of the peripheral interrupt with the Nested Vectored Interrupt Controller and control of the peripheral clock with the Power Management Controller.

**Table 14-1. Peripheral Identifiers**

| Instance ID | Instance Name | NVIC Interrupt | PMC Clock Control | Description   |
|-------------|---------------|----------------|-------------------|---|
| 0           | SUPC          | X              | –                 | Supply Controller                                       |
| 1           | RSTC          | X              | –                 | Reset Controller  |
| 2           | RTC           | X              | –                 | Real Time Clock   |
| 3           | RTT           | X              | –                 | Real Time Timer   |
| 4           | WDT           | X              | –                 | Watchdog Timer  |
| 5           | PMC           | X              | –                 | Power Management Controller                             |
| 6           | EFC           | X              | –                 | Enhanced Embedded Flash Controller                      |
| 7           | UART0         | X              | X                 | Universal Asynchronous Receiver/Transmitter             |
| 8           | UART1         | X              | X                 | Universal Asynchronous Receiver/Transmitter             |
| 9           | SMC           | –              | X                 | Static Memory Controller                                |
| 10          | PIOA          | X              | X                 | Parallel I/O Controller A                               |
| 11          | PIOB          | X              | X                 | Parallel I/O Controller B                               |
| 12          | PIOC          | X              | X                 | Parallel I/O Controller C                               |

## 14.2 Peripheral Signal Multiplexing on I/O Lines

The SAM E70/S70/V70/V71 features

- Two PIO controllers on 64-pin versions (PIOA and PIOB)
- Three PIO controllers on the 100-pin version (PIOA, PIOB and PIOD)
- Five PIO controllers on the 144-pin version (PIOA, PIOB, PIOC, PIOD and PIOE), that multiplex the I/O lines of the peripheral set.

The SAM E70/S70/V70/V71 PIO Controllers control up to 32 lines and each line can be assigned to one of four peripheral functions: A, B, C or D.

For more information on multiplexed signals, refer to the [“Package and Pinout”](#) chapter.

## 15. Arm Cortex-M7

Refer to Arm reference documents *Cortex-M7 Processor User Guide* (ARM DUI 0644) and *Cortex-M7 Technical Reference Manual* (ARM DDI 0489), which are available for download at [www.arm.com](http://www.arm.com).

### 15.1 Arm Cortex-M7 Configuration

The following table provides the configuration for the Arm Cortex-M7 processor in SAM E70/S70/V70/V71 devices.

**Table 15-1. Arm Cortex-M7 Configuration**

| Features                       | Configuration                                     |
|--------------------------------|---|
| <b>Debug</b>                   |   |
| Comparator set                 | Full comparator set: 4 DWT and 8 FPB comparators  |
| ETM support                    | Instruction ETM interface                         |
| Internal Trace support (ITM)   | ITM and DWT trace functionality implemented       |
| CTI and WIC                    | Not embedded                                      |
| <b>TCM</b>                     |   |
| ITCM max size                  | 128 KB  |
| DTCM max size                  | 256 KB  |
| <b>Cache</b>                   |   |
| Cache size                     | 16 KB for instruction cache, 16 KB for data cache |
| Number of sets                 | 256 for instruction cache, 128 for data cache     |
| Number of ways                 | 2 for instruction cache, 4 for data cache         |
| Number of words per cache line | 8 words (32 bytes)                                |
| ECC on Cache                   | Embedded  |
| <b>NVIC</b>                    |   |
| IRQ number                     | 74  |
| IRQ priority levels            | 8   |
| <b>MPU</b>                     |   |
| Number of regions              | 16  |
| <b>FPU</b>                     |   |
| FPU precision                  | Single and double precision                       |
| <b>AHB Port</b>                |   |
| AHBP addressing size           | 512 MB  |

## **16. Debug and Test Features**

### **16.1 Description**

The device features a number of complementary debug and test capabilities. The Serial Wire Debug Port (SW-DP) is used for standard debugging functions, such as downloading code and single-stepping through programs. It also embeds a serial wire trace.

### **16.2 Embedded Characteristics**

- Debug access to all memory and registers in the system, including Cortex-M register bank, when the core is running, halted, or held in reset.
- Serial Wire Debug Port (SW-DP) debug access (ADIV5.1 with no multidrop mode support).
- Flash Patch and Breakpoint (FPB) unit for implementing breakpoints and code patches.
- Data Watchpoint and Trace (DWT) unit for implementing watchpoints, data tracing, and system profiling.
- Instrumentation Trace Macrocell (ITM) for support of printf style debugging.
- 6-pin Embedded Trace Macrocell (ETM) for instruction trace stream, including CoreSight™ Trace Port Interface Unit (TPIU).
- IEEE1149.1 JTAG Boundary scan on All Digital Pins.

### **16.3 Associated Documents**

The SAM E70/S70/V70/V71 implements the standard Arm CoreSight macrocell. For information on CoreSight, the following reference documents are available from the Arm web site ([www.arm.com](http://www.arm.com)):

- Cortex-M7 User Guide Reference Manual (ARM DUI 0644)
- Cortex-M7 Technical Reference Manual (ARM DDI 0489)
- CoreSight Technology System Design Guide (ARM DGI 0012)
- CoreSight Components Technical Reference Manual (ARM DDI 0314)
- ARM Debug Interface v5 Architecture Specification (Doc. ARM IHI 0031)
- ARMv7-M Architecture Reference Manual (ARM DDI 0403)

### 16.4 Debug and Test Block Diagram

Figure 16-1. Debug and Test Block Diagram

### 16.5 Debug and Test Pin Description

Table 16-1. Debug and Test Signal List

| Signal Name                                      | Function                                  | Type         | Active Level |
|--|---|--------------|--------------|
| <b>Reset/Test</b>                                |   |              |              |
| NRST   | Microcontroller Reset                     | Input/Output | Low          |
| TST  | Test Select                               | Input        | –            |
| <b>Serial Wire Debug Port/JTAG Boundary Scan</b> |   |              |              |
| TCK/SWCLK  | Test Clock/Serial Wire Clock              | Input        | –            |
| TDI  | Test Data In                              | Input        | –            |
| TDO/TRACESWO                                     | Test Data Out/Trace Asynchronous Data Out | Output       | –            |
| TMS/SWDIO  | Test Mode Select/Serial Wire Input/Output | Input        | –            |
| JTAGSEL  | JTAG Selection                            | Input        | High         |
| <b>Trace Debug Port</b>                          |   |              |              |
| TRACECLK   | Trace Clock                               | Output       | –            |
| TRACED0–3  | Trace Data                                | Output       | –            |

## 16.6 Application Examples

### 16.6.1 Debug Environment

The figure below shows a complete debug environment example. The SW-DP interface is used for standard debugging functions, such as downloading code and single-stepping through the program and viewing core and peripheral registers.

**Figure 16-2. Application Debug Environment Example**

### 16.6.2 Test Environment

The figure below shows a test environment example (JTAG Boundary scan). Test vectors are sent and interpreted by the tester. In this example, the “board in test” is designed using a number of JTAG-compliant devices. These devices can be connected to form a single scan chain.

**Figure 16-3. Application Test Environment Example**

## 16.7 Functional Description

### 16.7.1 Test Pin

The TST pin is used for JTAG Boundary Scan Manufacturing Test or Fast Flash Programming mode. The TST pin integrates a permanent pulldown resistor of about 15 kΩ to GND, so that it can be left unconnected for normal operations. To enable Fast Flash Programming mode, refer to [18. Fast Flash Programming Interface \(FFPI\)](#).

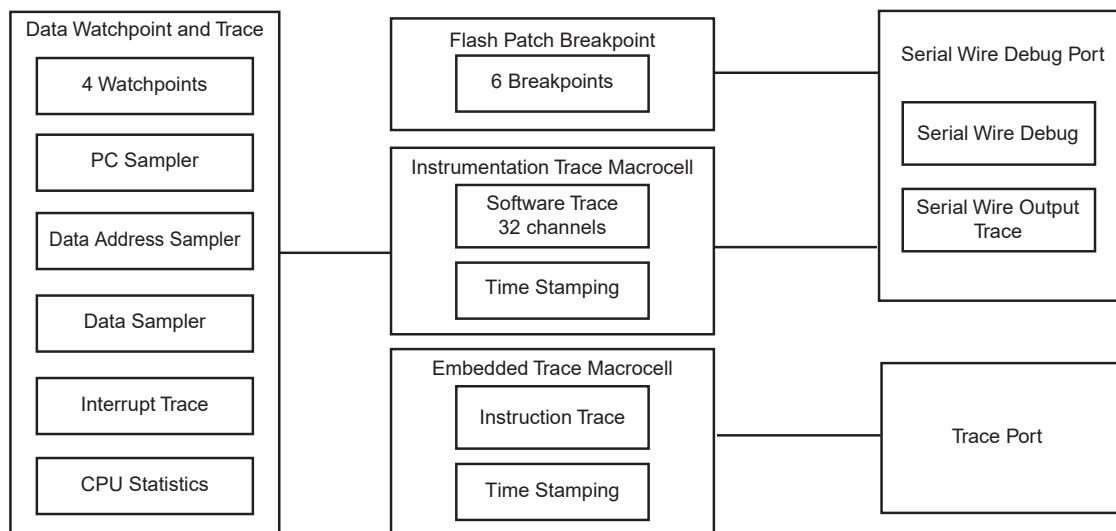

### 16.7.2 Debug Architecture

Figure 16-4 shows the debug architecture used. The Cortex-M7 embeds six functional units for debug:

- Serial Wire Debug Port (SW-DP) debug access
- FPB (Flash Patch Breakpoint)
- DWT (Data Watchpoint and Trace)
- ITM (Instrumentation Trace Macrocell)
- 6-pin Embedded Trace Macrocell (ETM) for instruction trace stream, including CoreSight Trace Port Interface Unit (TPIU)
- IEEE1149.1 JTAG Boundary scan on all digital pins

The debug architecture information that follows is mainly dedicated to developers of SW-DP Emulators/Probes and debugging tool vendors for Cortex-M7-based microcontrollers. For further details on SW-DP, see the Cortex - M7 Technical Reference Manual.

**Figure 16-4. Debug Architecture**

### 16.7.3 Serial Wire Debug Port (SW-DP) Pins

The SW-DP pins SWCLK and SWDIO are commonly provided on a standard 20-pin JTAG connector defined by ARM. For more details on voltage reference and reset state, refer to the ["Signal Description"](#) chapter.

At startup, SW-DP pins are configured in SW-DP mode to allow connection with debugging probe.

SW-DP pins can be used as standard I/Os to provide users more general input/output pins when the debug port is not needed in the end application. Mode selection between SW-DP mode (System I/O mode) and general I/O mode is performed through the AHB Matrix Chip Configuration registers (CCFG\_SYSIO). Configuration of the pad for pullup, triggers, debouncing and glitch filters is possible regardless of the mode.

The JTAGESSEL pin is used to select the JTAG boundary scan when asserted at a high level. It integrates a permanent pulldown resistor of about 15 kΩ to GND, so that it can be left unconnected for normal operations.

The JTAG debug ports TDI, TDO, TMS and TCK are inactive. They are provided for Boundary Scan Manufacturing Test purposes only. By default the SW-DP is active; TDO/TRACESWO can be used for trace.

**Table 16-2. SW-DP Pin List**

| Pin Name     | JTAG Boundary Scan | Serial Wire Debug Port     |
|--------------|--------------------|----------------------------|
| TMS/SWDIO    | TMS                | SWDIO                      |
| TCK/SWCLK    | TCK                | SWCLK                      |
| TDI          | TDI                | –                          |
| TDO/TRACESWO | TDO                | TRACESWO (optional: trace) |

SW-DP is selected when JTAGSEL is low. It is not possible to switch directly between SW-DP and JTAG boundary scan operations. A chip reset must be performed after JTAGSEL is changed.

### 16.7.4 Embedded Trace Module (ETM) Pins

The Embedded Trace Module (ETM) uses the Trace Port Interface Unit (TPIU) to export data out of the system.

The TPUI features the pins:

- TRACECLK—always exported to enable synchronization back with the data. PCK3 is used internally.
- TRACED0–3—the instruction trace stream.

### 16.7.5 Flash Patch Breakpoint (FPB)

The FPB implements hardware breakpoints.

### 16.7.6 Data Watchpoint and Trace (DWT)

The DWT contains four comparators which can be configured to generate:

- PC sampling packets at set intervals
- PC or Data watchpoint packets
- Watchpoint event to halt core

The DWT contains counters for:

- Clock cycle (CYCCNT)
- Folded instructions
- Load Store Unit (LSU) operations
- Sleep cycles
- CPI (all instruction cycles except for the first cycle)
- Interrupt overhead

### 16.7.7 Instrumentation Trace Macrocell (ITM)

The ITM is an application driven trace source that supports `printf` style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets which can be generated by three different sources with several priority levels:

- Software trace: Software can write directly to ITM stimulus registers. This can be done using the `printf` function. For more information, refer to [16.7.5. Flash Patch Breakpoint \(FPB\)](#).
- Hardware trace: The ITM emits packets generated by the DWT.
- Timestamping: Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp.

#### 16.7.7.1 How to Configure the ITM

The following example describes how to output trace data in asynchronous trace mode.

Configure the TPIU for asynchronous trace mode. Refer to [16.7.7.3. How to Configure the TPIU](#).

1. Enable the write accesses into the ITM registers by writing “0xC5ACCE55” into the Lock Access Register (Address: 0xE000FB0)
2. Write 0x00010015 into the Trace Control register:

- Enable ITM.
  - Enable Synchronization packets.
  - Enable SWO behavior.
  - Fix the ATB ID to 1.
3. Write 0x1 into the Trace Enable register:
    - Enable the Stimulus port 0.
  4. Write 0x1 into the Trace Privilege register:
    - Stimulus port 0 only accessed in privileged mode (Clearing a bit in this register will result in the corresponding stimulus port being accessible in user mode.)
  5. Write into the Stimulus port 0 register: TPIU (Trace Port Interface Unit)  
The TPIU acts as a bridge between the on-chip trace data and the Instruction Trace Macrocell (ITM).  
The TPIU formats and transmits trace data off-chip at frequencies asynchronous to the core.

### 16.7.7.2 Asynchronous Mode

The TPIU is configured in asynchronous mode, trace data are output using the single TRACESWO pin. The TRACESWO signal is multiplexed with the TDO signal. As a consequence, asynchronous trace mode is only available when the Serial Wire Debug mode is selected.

Two encoding formats are available for the single pin output:

- Manchester encoded stream. This is the reset value.
- NRZ\_based UART byte structure

### 16.7.7.3 How to Configure the TPIU

This example only concerns the asynchronous trace mode.

Set the TRCENA bit to 1 into the Debug Exception and Monitor Register (0xE000EDFC) to enable the use of trace and debug blocks.

1. Write 0x2 into the Selected Pin Protocol Register.
  - Select the Serial Wire output – NRZ
2. Write 0x100 into the Formatter and Flush Control Register.
3. Set the suitable clock prescaler value into the Async Clock Prescaler Register to scale the baud rate of the asynchronous output (this can be done automatically by the debugging tool).

### 16.7.8 IEEE1149.1 JTAG Boundary Scan

IEEE1149.1 JTAG Boundary Scan allows pin-level access independent of the device packaging technology.

IEEE1149.1 JTAG Boundary Scan is enabled when TST is tied to high, PD0 tied to low, and JTAGSEL tied to high during powerup. These pins must be maintained in their respective states for the duration of the boundary scan operation. The SAMPLE, EXTEST and BYPASS functions are implemented. In Serial Wire Debug mode, the ARM processor responds with a non-JTAG chip ID that identifies the processor. This is not IEEE1149.1 JTAG-compliant.

It is not possible to switch directly between JTAG Boundary Scan and SWJ Debug Port operations. A chip reset must be performed after JTAGSEL is changed.

A Boundary Scan Descriptor Language (BSDL) file to set up the test is provided on [www.microchip.com](http://www.microchip.com).

#### 16.7.8.1 JTAG Boundary Scan Register

The Boundary Scan Register (BSR) contains a number of bits which correspond to active pins and associated control signals.

Each input/output pin corresponds to a 3-bit register in the BSR. The OUTPUT bit contains data that can be forced on the pad. The INPUT bit facilitates the observability of data applied to the pad. The CONTROL bit selects the direction of the pad.

For more information, refer to BSDL files available on [www.microchip.com](http://www.microchip.com).

### 16.7.9 ID Code Register

**Access:** Read-only

## 17. SAM-BA Boot Program

### 17.1 Description

The SAM-BA Boot Program integrates an array of programs permitting download and/or upload into the different memories of the product.

### 17.2 Embedded Characteristics

- Default Boot program
- Interface with SAM-BA graphic user interface (GUI)
- SAM-BA Boot
  - Supports several communication media:
    - Serial Communication on UART0
    - USB device port communication up to 1Mbyte/s
  - USB Requirements:
    - External crystal or external clock with frequency of 12 MHz or 16 MHz

### 17.3 Hardware and Software Constraints

- SAM-BA Boot uses the first 2048 bytes of the SRAM for variables and stacks. The remaining available bytes can be used for the user code.
  - USB requirements:
    - External crystal or external clock (see **Note** below) with frequency of 12 MHz or 16 MHz
- Note:** Must be 2500 ppm and VDDIO square wave signal.
- UART0 requirements:
    - None. If accurate external clock source is not available, the internal 12 MHz RC meets RS-232 standards at room temperature.

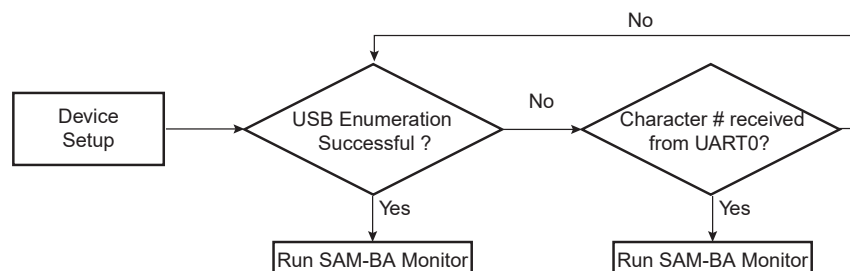

**Table 17-1. Pins Driven during Boot Program Execution**

| Peripheral | Pin   | PIO Line |
|------------|-------|----------|
| UART0      | URXD0 | PA9      |
| UART0      | UTXD0 | PA10     |

### 17.4 Flow Diagram

The boot program implements the algorithm below.

**Figure 17-1. Boot Program Algorithm Flow Diagram**

The SAM-BA boot program looks for a source clock, either from the embedded main oscillator with external crystal (main oscillator enabled) or from a supported frequency signal applied to the XIN pin (Main oscillator in bypass mode).

If a clock is supplied by one of the two sources, the boot program checks that the frequency is one of the supported external frequencies. If the frequency is supported, USB activation is allowed. If no clock is supplied, or if a clock is supplied but the frequency is not a supported external frequency, the internal 12 MHz RC oscillator is used as the main clock. In this case, the USB is not activated due to the frequency drift of the 12 MHz RC oscillator.

## 17.5 Device Initialization

Initialization by the boot program follows the steps described below:

Stack setup.

1. Embedded Flash Controller setup.
2. External clock (crystal or external clock on XIN) detection.
3. External crystal or clock with supported frequency supplied.
  - a. If yes, USB activation is allowed.
  - b. If no, USB activation is not allowed. The internal 12 MHz RC oscillator is used.
4. Host clock switch to main oscillator.
5. C variable initialization.
6. PLLA setup: PLLA is initialized to generate a 48 MHz clock.
7. Watchdog disable.
8. Initialization of UART0 (115200 bauds, 8, N, 1).
9. Initialization of the USB Device Port (only if USB activation is allowed; see [Step 4](#)).
10. Wait for one of the following events:
  - a. Check if USB device enumeration has occurred.
  - b. Check if characters have been received in UART0.
11. Jump to SAM-BA Monitor (refer to [17.6. SAM-BA Monitor](#))

## 17.6 SAM-BA Monitor

Once the communication interface is identified, the monitor runs in an infinite loop, waiting for different commands, as shown in the following table.

**Table 17-2. Commands Available through the SAM-BA Boot**

| Command | Action            | Arguments           | Example           |
|---------|-------------------|---------------------|-------------------|
| N       | Set Normal mode   | No argument         | N#                |
| T       | Set Terminal mode | No argument         | T#                |
| O       | Write a byte      | Address, Value#     | O200001,CA#       |
| o       | Read a byte       | Address,#           | o200001,#         |
| H       | Write a half word | Address, Value#     | H200002,CAFE#     |
| h       | Read a half word  | Address,#           | h200002,#         |
| W       | Write a word      | Address, Value#     | W200000,CAFEBECA# |
| w       | Read a word       | Address,#           | w200000,#         |
| S       | Send a file       | Address,#           | S200000,#         |
| R       | Receive a file    | Address, NbOfBytes# | R200000,1234#     |

| .....continued |                 |             |          |
|----------------|-----------------|-------------|----------|
| Command        | Action          | Arguments   | Example  |
| G              | Go              | Address#    | G200200# |
| V              | Display version | No argument | V#       |

- Mode commands:
  - Normal mode configures SAM-BA Monitor to send/receive data in binary format
  - Terminal mode configures SAM-BA Monitor to send/receive data in ASCII format
- Write commands: Write a byte (O), a halfword (H) or a word (W) to the target
  - Address: Address in hexadecimal
  - Value: Byte, halfword or word to write in hexadecimal
- Read commands: Read a byte (o), a halfword (h) or a word (w) from the target
  - Address: Address in hexadecimal
  - Output: The byte, halfword or word read in hexadecimal
- Send a file (S): Send a file to a specified address
  - Address: Address in hexadecimal
  - Note:** There is a timeout on this command which is reached when the prompt '>' appears before the end of the command execution.
- Receive a file (R): Receive data into a file from a specified address
  - Address: Address in hexadecimal
  - NbOfBytes: Number of bytes in hexadecimal to receive
- Go (G): Jump to a specified address and execute the code
  - Address: Address to jump in hexadecimal
- Get Version (V): Return the SAM-BA boot version
  - Note:** In Terminal mode, when the requested command is performed, SAM-BA Monitor adds the following prompt sequence to its answer: <LF>+<CR>+>'.

### 17.6.1 UART0 Serial Port

Communication is performed through the UART0 initialized to 115200 Baud, 8, n, 1.

The Send and Receive File commands use the Xmodem protocol to communicate. Any terminal performing this protocol can be used to send the application file to the target. The size of the binary file to send depends on the SRAM size embedded in the product. In all cases, the size of the binary file must be smaller than the SRAM size because the Xmodem protocol requires some SRAM memory to work. Refer to the ["Hardware and Software Constraints"](#) section.

### 17.6.2 Xmodem Protocol

The Xmodem protocol supported is the 128-byte length block. This protocol uses a two-character CRC-16 to guarantee detection of a maximum bit error.

The Xmodem protocol with CRC is accurate if both sender and receiver report successful transmission. Each block of the transfer has the following format:

<SOH><blk #><255-blk #><--128 data bytes--><checksum> in which:

- <SOH> = 01 hex
- <blk #> = binary number, starts at 01, increments by 1, and wraps 0FFH to 00H (not to 01)
- <255-blk #> = 1's complement of the blk#.
- <checksum> = 2 bytes CRC16

The figure below shows a transmission using this protocol.

**Figure 17-2. Xmodem Transfer Example**

### 17.6.3 USB Device Port

The device uses the USB communication device class (CDC) drivers to take advantage of the installed PC RS-232 software to talk over the USB. The CDC class is implemented in all releases of Windows®, beginning with Windows 98SE. The CDC document, available at [www.usb.org](http://www.usb.org), describes a way to implement devices such as ISDN modems and virtual COM ports.

The Vendor ID (VID) is the Atmel vendor ID 0x03EB. The product ID (PID) is 0x6124. These references are used by the host operating system to mount the correct driver. On Windows systems, the INF files contain the correspondence between vendor ID and product ID.

For more details on VID/PID for end product/systems, refer to the Vendor ID form available from the USB Implementers Forum found at <http://www.usb.org/>.

Unauthorized use of assigned or unassigned USB Vendor ID Numbers and associated Product ID Numbers is strictly prohibited.

#### 17.6.3.1 Enumeration Process

The USB protocol is a Host/Client protocol. This is the host that starts the enumeration sending requests to the device through the control endpoint. The device handles standard requests as defined in the USB Specification.

**Table 17-3. Handled Standard Requests**

| Request           | Definition  |
|-------------------|---|
| GET_DESCRIPTOR    | Returns the current device configuration value.       |
| SET_ADDRESS       | Sets the device address for all future device access. |
| SET_CONFIGURATION | Sets the device configuration.                        |
| GET_CONFIGURATION | Returns the current device configuration value.       |
| GET_STATUS        | Returns status for the specified recipient.           |
| SET_FEATURE       | Set or Enable a specific feature.                     |
| CLEAR_FEATURE     | Clear or Disable a specific feature.                  |

The device also handles some class requests defined in the CDC class.

**Table 17-4. Handled Class Requests**

| Request                | Definition   |
|------------------------|--|
| SET_LINE_CODING        | Configures DTE rate, stop bits, parity and number of character bits.       |
| GET_LINE_CODING        | Requests current DTE rate, stop bits, parity and number of character bits. |
| SET_CONTROL_LINE_STATE | RS-232 signal used to tell the DCE device the DTE device is now present.   |

Unhandled requests are STALLED.

### 17.6.3.2 Communication Endpoints

There are two communication endpoints. Endpoint 0 is used for the enumeration process. Endpoint 1 is a 64-byte Bulk OUT endpoint. Endpoint 2 is a 64-byte Bulk IN endpoint. SAM-BA Boot commands are sent by the host through endpoint 1. If required, the message is split by the host into several data payloads by the host driver.

If the command requires a response, the host can send IN transactions to pick up the response.

### 17.6.4 In Application Programming (IAP) Feature

The IAP feature is a function located in ROM that can be called by any software application.

When called, this function sends the desired FLASH command to the EEFC and waits for the Flash to be ready (looping while the FRDY bit is not set in the MC\_FSR register).

Since this function is executed from ROM, this allows Flash programming (such as sector write) to be done by code running in Flash.

The IAP function entry point is retrieved by reading the NMI vector in ROM (0x00800008).

This function takes two arguments as parameters:

- the index of the Flash bank to be programmed: 0 for EEFC0, 1 for EEFC1. For devices with only one bank, this parameter has no effect and can be either 0 or 1, only EEFC0 will be accessed.
- the command to be sent to the EEFC Command register.

This function returns the value of the EEFC\_FSR register.

An example of IAP software code follows:

```
// Example: How to write data in page 200 of the flash memory using ROM IAP function
flash_page_num = 200
flash_cmd = 0
flash_status = 0
eefc_index = 0 (0 for EEFC0, 1 for EEFC1)
// Initialize the function pointer (retrieve function address from NMI vector)*/
iap_function_address = 0x00800008
// Fill the Flash page buffer at address 200 with the data to be written
for i=0, i < page_size, i++ do
flash_sector_200_address[i] = your_data[i]
// Prepare the command to be sent to the EEFC Command register: key, page number and
write command
flash_cmd = (0x5A << 24) | (flash_page_num << 8) | flash_write_command;
// Call the IAP function with the right parameters and retrieve the status in
flash_status after completion
flash_status = iap_function (eefc_index, flash_cmd);
```

## 18. Fast Flash Programming Interface (FFPI)

### 18.1 Description

The Fast Flash Programming Interface (FFPI) provides parallel high-volume programming using a standard gang programmer. The parallel interface is fully handshaked and the device is considered to be a standard EEPROM. Additionally, the parallel protocol offers an optimized access to all the embedded Flash functionalities.

Although the Fast Flash Programming mode is a dedicated mode for high volume programming, this mode is not designed for in-situ programming.

### 18.2 Embedded Characteristics

- Programming Mode for High-volume Flash Programming Using Gang Programmer
  - Offers Read and Write Access to the Flash Memory Plane
  - Enables Control of Lock Bits and General-purpose NVM Bits
  - Enables Security Bit Activation
  - Disabled Once Security Bit is Set
- Parallel Fast Flash Programming Interface
  - Provides a 16-bit Parallel Interface to Program the Embedded Flash
  - Full Handshake Protocol

### 18.3 Parallel Fast Flash Programming

#### 18.3.1 Device Configuration

In Fast Flash Programming mode, the device is in a specific test mode. Only a certain set of pins is significant. The rest of the PIOs are used as inputs with a pullup. The crystal oscillator is in Bypass mode, an external clock must be provided on the XIN pin.

**Figure 18-1. 16-bit Parallel Programming Interface**

**Table 18-1. Signal Description List**

| Signal Name | Function | Type | Active Level | Comments |
|-------------|----------|------|--------------|----------|
| Power       |          |      |              |          |

# SAM E70/S70/V70/V71

## Fast Flash Programming Interface (FFPI)

.....continued

| Signal Name | Function  | Type         | Active Level | Comments                   |
|-------------|---|--------------|--------------|----------------------------|
| VDDIO       | I/O Lines Power Supply  | Power        | –            | –                          |

| Test        |   |              |              |                            |
| TST         | Test Mode Select  | Input        | High         | Must be connected to VDDIO |
| PGMEN0      | Test Mode Select  | Input        | Low          | Must be connected to VDDIO |
| PGMEN1      | Test Mode Select  | Input        | High         | Must be connected to VDDIO |
| PIO         |   |              |              |                            |
| PGMNCMD     | Valid command available   | Input        | Low          | Pulled-up input at reset   |
| PGMRDY      | 0: Device is busy<br>1: Device is ready for a new command         | Output       | High         | Pulled-up input at reset   |
| PGMNOE      | Output Enable (active high)                                       | Input        | Low          | Pulled-up input at reset   |
| PGMNVALID   | 0: DATA[15:0] is in input mode<br>1: DATA[15:0] is in output mode | Output       | Low          | Pulled-up input at reset   |
| PGMM[3:0]   | Specifies DATA type (see <a href="#">Table 18-2</a> )             | Input        | –            | Pulled-up input at reset   |
| PGMD[15:0]  | Bidirectional data bus  | Input/Output | –            | Pulled-up input at reset   |

### 18.3.2 Signal Names

Depending on the MODE settings, DATA is latched in different internal registers.

**Table 18-2. Mode Coding**

| MODE[3:0] | Symbol | Data                  |
|-----------|--------|-----------------------|
| 0000      | CMDE   | Command Register      |
| 0001      | ADDR0  | Address Register LSBs |
| 0010      | ADDR1  | –                     |
| 0011      | ADDR2  | –                     |
| 0100      | ADDR3  | Address Register MSBs |
| 0101      | DATA   | Data Register         |
| Default   | IDLE   | No register           |

When MODE is equal to CMDE, then a new command (strobed on DATA[15:0] signals) is stored in the command register.

**Table 18-3. Command Bit Coding**

| DATA[15:0] | Symbol | Command Executed |
|------------|--------|------------------|
| 0x0011     | READ   | Read Flash       |

# SAM E70/S70/V70/V71

## Fast Flash Programming Interface (FFPI)

| .....continued |        |                                     |
|----------------|--------|-------------------------------------|
| DATA[15:0]     | Symbol | Command Executed                    |
| 0x0012         | WP     | Write Page Flash                    |
| 0x0022         | WPL    | Write Page and Lock Flash           |
| 0x0032         | EWP    | Erase Page and Write Page           |
| 0x0042         | EWPL   | Erase Page and Write Page then Lock |
| 0x0013         | EA     | Erase All                           |
| 0x0014         | SLB    | Set Lock Bit                        |
| 0x0024         | CLB    | Clear Lock Bit                      |
| 0x0015         | GLB    | Get Lock Bit                        |
| 0x0034         | SGPB   | Set General Purpose NVM bit         |
| 0x0044         | CGPB   | Clear General Purpose NVM bit       |
| 0x0025         | GGPB   | Get General Purpose NVM bit         |
| 0x0054         | SSE    | Set Security Bit                    |
| 0x0035         | GSE    | Get Security Bit                    |
| 0x001F         | WRAM   | Write Memory                        |
| 0x001E         | GVE    | Get Version                         |

### 18.3.3 Entering Parallel Programming Mode

The following algorithm puts the device in Parallel Programming mode:

1. Apply the supplies as described in table [Signal Description List](#).
2. External clock is applied to the XIN pin within the VDDCORE POR reset time-out period, as defined in the section “Electrical Characteristics”.
3. Wait for the end of this reset period.
4. Start a read or write handshaking.

### 18.3.4 Programmer Handshaking

A handshake is defined for read and write operations. When the device is ready to start a new operation (RDY signal set), the programmer starts the handshake by clearing the NCMD signal. The handshaking is completed once the NCMD signal is high and RDY is high.

#### 18.3.4.1 Write Handshaking

For details on the write handshaking sequence, refer to the following figure and table.

**Figure 18-2. Parallel Programming Timing, Write Sequence**

**Table 18-4. Write Handshake**

| Step | Programmer Action              | Device Action                        | Data I/O |
|------|--------------------------------|--------------------------------------|----------|
| 1    | Sets MODE and DATA signals     | Waits for NCMD low                   | Input    |
| 2    | Clears NCMD signal             | Latches MODE and DATA                | Input    |
| 3    | Waits for RDY low              | Clears RDY signal                    | Input    |
| 4    | Releases MODE and DATA signals | Executes command and polls NCMD high | Input    |
| 5    | Sets NCMD signal               | Executes command and polls NCMD high | Input    |
| 6    | Waits for RDY high             | Sets RDY                             | Input    |

### 18.3.4.2 Read Handshaking

For details on the read handshaking sequence, refer to the following figure and table.

**Figure 18-3. Parallel Programming Timing, Read Sequence**

**Table 18-5. Read Handshake**

| Step | Programmer Action          | Device Action       | DATA I/O |
|------|----------------------------|---------------------|----------|
| 1    | Sets MODE and DATA signals | Waits for NCMD low  | Input    |
| 2    | Clears NCMD signal         | Latch MODE and DATA | Input    |
| 3    | Waits for RDY low          | Clears RDY signal   | Input    |

# SAM E70/S70/V70/V71

## Fast Flash Programming Interface (FFPI)

.....continued

| Step | Programmer Action            | Device Action  | DATA I/O |
|------|------------------------------|--|----------|
| 4    | Sets DATA signal in tristate | Waits for NOE Low  | Input    |
| 5    | Clears NOE signal            | –  | Tristate |
| 6    | Waits for NVALID low         | Sets DATA bus in output mode and outputs the flash contents. | Output   |
| 7    | –                            | Clears NVALID signal   | Output   |
| 8    | Reads value on DATA Bus      | Waits for NOE high   | Output   |
| 9    | Sets NOE signal              | –  | Output   |
| 10   | Waits for NVALID high        | Sets DATA bus in input mode                                  | X        |
| 11   | Sets DATA in output mode     | Sets NVALID signal   | Input    |
| 12   | Sets NCMD signal             | Waits for NCMD high  | Input    |
| 13   | Waits for RDY high           | Sets RDY signal  | Input    |

### 18.3.5 Device Operations

Several commands on the Flash memory are available. These commands are summarized in table [Command Bit Coding](#). Each command is driven by the programmer through the parallel interface running several read/write handshaking sequences.

When a new command is executed, the previous one is automatically achieved. Thus, chaining a read command after a write automatically flushes the load buffer in the Flash.

#### 18.3.5.1 Flash Read Command

This command is used to read the contents of the Flash memory. The read command can start at any valid address in the memory plane and is optimized for consecutive reads. Read handshaking can be chained; an internal address buffer is automatically increased.

**Table 18-6. Read Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0]         |
|------|--------------------|-----------|--------------------|
| 1    | Write handshaking  | CMDE      | READ               |
| 2    | Write handshaking  | ADDR0     | Memory Address LSB |
| 3    | Write handshaking  | ADDR1     | Memory Address     |
| 4    | Read handshaking   | DATA      | *Memory Address++  |
| 5    | Read handshaking   | DATA      | *Memory Address++  |
| ...  | ...                | ...       | ...                |
| n    | Write handshaking  | ADDR0     | Memory Address LSB |
| n+1  | Write handshaking  | ADDR1     | Memory Address     |
| n+2  | Read handshaking   | DATA      | *Memory Address++  |
| n+3  | Read handshaking   | DATA      | *Memory Address++  |
| ...  | ...                | ...       | ...                |

#### 18.3.5.2 Flash Write Command

The Flash Write command is used to write the Flash contents.

The Flash memory plane is organized into several pages. Data to be written are stored in a load buffer that corresponds to a Flash memory page. The load buffer is automatically flushed to the Flash:

# SAM E70/S70/V70/V71

## Fast Flash Programming Interface (FFPI)

- Before access to any page other than the current one
- When a new command is validated (MODE = CMDE)

The Write Page command (WP) is optimized for consecutive writes. Write handshaking can be chained; an internal address buffer is automatically increased. An additional WP command must be executed if a full page is not written or if the write data starts from a non-zero page offset.

**Table 18-7. Write Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0]               |
|------|--------------------|-----------|--------------------------|
| 1    | Write handshaking  | CMDE      | WP or WPL or EWP or EWPL |
| 2    | Write handshaking  | ADDR0     | Memory Address LSB       |
| 3    | Write handshaking  | ADDR1     | Memory Address           |
| 4    | Write handshaking  | DATA      | *Memory Address++        |
| 5    | Write handshaking  | DATA      | *Memory Address++        |
| ...  | ...                | ...       | ...                      |
| n    | Write handshaking  | ADDR0     | Memory Address LSB       |
| n+1  | Write handshaking  | ADDR1     | Memory Address           |
| n+2  | Write handshaking  | DATA      | *Memory Address++        |
| n+3  | Write handshaking  | DATA      | *Memory Address++        |
| ...  | ...                | ...       | ...                      |

The Flash command Write Page and Lock (WPL) is equivalent to the Flash Write Command. However, the lock bit is automatically set at the end of the Flash write operation. As a lock region is composed of several pages, the programmer writes to the first pages of the lock region using Flash write commands and writes to the last page of the lock region using a Flash write and lock command.

The Flash command Erase Page and Write (EWP) is equivalent to the Flash Write Command. However, before programming the load buffer, the page is erased.

The Flash command Erase Page and Write the Lock (EWPL) combines EWP and WPL commands.

### 18.3.5.3 Flash Full Erase Command

This command is used to erase the Flash memory planes.

All lock regions must be unlocked before the Full Erase command by using the CLB command. Otherwise, the erase command is aborted and no page is erased.

**Table 18-8. Full Erase Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0] |
|------|--------------------|-----------|------------|
| 1    | Write handshaking  | CMDE      | EA         |
| 2    | Write handshaking  | DATA      | 0          |

### 18.3.5.4 Flash Lock Commands

Lock bits can be set using WPL or EWPL commands. They can also be set by using the Set Lock command (SLB). With this command, several lock bits can be activated. A Bit Mask is provided as argument to the command. When bit 0 of the bit mask is set, then the first lock bit is activated.

In the same way, the Clear Lock command (CLB) is used to clear lock bits.

**Table 18-9. Set and Clear Lock Bit Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0] |
|------|--------------------|-----------|------------|
| 1    | Write handshaking  | CMDE      | SLB or CLB |
| 2    | Write handshaking  | DATA      | Bit Mask   |

Lock bits can be read using Get Lock Bit command (GLB). The  $n^{\text{th}}$  lock bit is active when the bit  $n$  of the bit mask is set.

**Table 18-10. Get Lock Bit Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0]   |
|------|--------------------|-----------|--|
| 1    | Write handshaking  | CMDE      | GLB  |
| 2    | Read handshaking   | DATA      | Lock Bit Mask Status<br>0 = Lock bit is cleared<br>1 = Lock bit is set |

### 18.3.5.5 Flash General-purpose NVM Commands

General-purpose NVM bits (GP NVM bits) can be set using the Set GPNVM command (SGPB). This command also activates GP NVM bits. A bit mask is provided as argument to the command. When bit 0 of the bit mask is set, then the first GP NVM bit is activated.

In the same way, the Clear GPNVM command (CGPB) is used to clear general-purpose NVM bits. The general-purpose NVM bit is deactivated when the corresponding bit in the pattern value is set to 1.

**Table 18-11. Set/Clear GP NVM Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0]               |
|------|--------------------|-----------|--------------------------|
| 1    | Write handshaking  | CMDE      | SGPB or CGPB             |
| 2    | Write handshaking  | DATA      | GP NVM bit pattern value |

General-purpose NVM bits can be read using the Get GPNVM Bit command (GGPB). The  $n^{\text{th}}$  GP NVM bit is active when bit  $n$  of the bit mask is set.

**Table 18-12. Get GP NVM Bit Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0]   |
|------|--------------------|-----------|--|
| 1    | Write handshaking  | CMDE      | GGPB   |
| 2    | Read handshaking   | DATA      | GP NVM Bit Mask Status<br>0 = GP NVM bit is cleared<br>1 = GP NVM bit is set |

### 18.3.5.6 Flash Security Bit Command

A security bit can be set using the Set Security Bit command (SSE). Once the security bit is active, the Fast Flash programming is disabled. No other command can be run. An event on the Erase signal can erase the security bit once the contents of the Flash have been erased.

**Table 18-13. Set Security Bit Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0] |
|------|--------------------|-----------|------------|
| 1    | Write handshaking  | CMDE      | SSE        |
| 2    | Write handshaking  | DATA      | 0          |

# SAM E70/S70/V70/V71

## Fast Flash Programming Interface (FFPI)

Once the security bit is set, it is not possible to access FFPI. The only way to erase the security bit is to erase the Flash.

To erase the Flash, perform the following steps:

1. Power off the chip.
2. Power on the chip with TST = 0.
3. Assert the ERASE signal for at least the ERASE pin assertion time as defined in the section “Electrical Characteristics”.
4. Power off the chip.

Return to FFPI mode to check that the Flash is erased.

### 18.3.5.7 Memory Write Command

This command is used to perform a write access to any memory location.

The Memory Write command (WRAM) is optimized for consecutive writes. Write handshaking can be chained; an internal address buffer is automatically increased.

**Table 18-14. Write Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0]         |
|------|--------------------|-----------|--------------------|
| 1    | Write handshaking  | CMDE      | WRAM               |
| 2    | Write handshaking  | ADDR0     | Memory Address LSB |
| 3    | Write handshaking  | ADDR1     | Memory Address     |
| 4    | Write handshaking  | DATA      | *Memory Address++  |
| 5    | Write handshaking  | DATA      | *Memory Address++  |
| ...  | ...                | ...       | ...                |
| n    | Write handshaking  | ADDR0     | Memory Address LSB |
| n+1  | Write handshaking  | ADDR1     | Memory Address     |
| n+2  | Write handshaking  | DATA      | *Memory Address++  |
| n+3  | Write handshaking  | DATA      | *Memory Address++  |
| ...  | ...                | ...       | ...                |

### 18.3.5.8 Get Version Command

The Get Version (GVE) command retrieves the version of the FFPI interface.

**Table 18-15. Get Version Command**

| Step | Handshake Sequence | MODE[3:0] | DATA[15:0] |
|------|--------------------|-----------|------------|
| 1    | Write handshaking  | CMDE      | GVE        |
| 2    | Read handshaking   | DATA      | Version    |

**Note:** GVE returned value is 0x29.

## 19. Bus Matrix (MATRIX)

### 19.1 Description

The Bus Matrix (MATRIX) implements a multi-layer AHB, based on the AHB-Lite protocol, that enables parallel access paths between multiple AHB Hosts and Clients in a system, thus increasing the overall bandwidth. The MATRIX interconnects 13 AHB Hosts to 9 AHB Clients. The normal latency to connect a Host to a Client is one cycle. The exception is the default Host of the accessed Client which is connected directly (zero cycle latency).

The MATRIX user interface is compliant with ARM Advanced Peripheral Bus.

### 19.2 Embedded Characteristics

- 13 Hosts
- 9 Clients
- One Decoder for Each Host
- Several Possible Boot Memories for Each Host before Remap
- One Remap Function for Each Host
- Support for Long Bursts of 32, 64, 128 and up to the 256-beat Word Burst AHB Limit
- Enhanced Programmable Mixed Arbitration for Each Client
  - Round-Robin
  - Fixed Priority
- Programmable Default Host for Each Client
  - No Default Host
  - Last Accessed Default Host
  - Fixed Default Host
- Deterministic Maximum Access Latency for Hosts
- Zero or One Cycle Arbitration Latency for the First Access of a Burst
- Bus Lock Forwarding to Clients
- Host Number Forwarding to Clients
- Configurable Automatic Clock-off Mode for Power Reduction
- One Special Function Register for Each Client (not dedicated)
- Register Write Protection

#### 19.2.1 Matrix Hosts

The MATRIX manages the Hosts listed in the following table. Each Host can perform an access to an available Client concurrently with other Hosts. lists the available Hosts.

Each Host has its own specifically-defined decoder. To simplify addressing, all the Hosts have the same decodings.

**Table 19-1. Bus Matrix Hosts**

| Host Index | Name                      |
|------------|---------------------------|
| 0          | Cortex-M7                 |
| 1          | Cortex-M7                 |
| 2          | Cortex-M7 Peripheral Port |
| 3          | Integrated Check Monitor  |
| 4, 5       | XDMAC                     |
| 6          | ISI DMA                   |

.....continued

| Host Index | Name             |
|------------|------------------|
| 7          | Media LB         |
| 8          | USB DMA          |
| 9          | Ethernet MAC DMA |
| 10         | CAN0 DMA         |
| 11         | CAN1 DMA         |
| 12         | Cortex-M7        |

**Note:** Host 12 (Cortex-M7) is only on revision B.

### 19.2.2 Matrix Clients

The MATRIX manages the Clients listed in the following table. Each Client has its own arbiter, providing a different arbitration per Client.

**Table 19-2. Bus Matrix Clients**

| Client Index | Name                               |
|--------------|------------------------------------|
| 0            | Internal SRAM                      |
| 1            | Internal SRAM                      |
| 2            | Internal ROM                       |
| 3            | Internal Flash                     |
| 4            | USB High Speed Dual Port RAM (DPR) |
| 5            | External Bus Interface             |
| 6            | QSPI                               |
| 7            | Peripheral Bridge                  |
| 8            | AHB Client                         |

### 19.2.3 Host to Client Access

The following table provides valid paths for Host to Client accesses. The paths shown as “-” are forbidden or not wired.

**Table 19-3. Host to Client Access**

| Hosts                  | 0         | 1         | 2                         | 3   | 4               | 5               | 6       | 7           | 8       | 9        | 10       | 11       | 12        |
|------------------------|-----------|-----------|---------------------------|-----|-----------------|-----------------|---------|-------------|---------|----------|----------|----------|-----------|
| Clients                | Cortex-M7 | Cortex-M7 | Cortex-M7 Peripheral Port | ICM | Central DMA IF0 | Central DMA IF1 | ISI DMA | MediaLB DMA | USB DMA | GMAC DMA | CAN0 DMA | CAN1 DMA | Cortex-M7 |
| 0 Internal SRAM        | -         | -         | -                         | X   | X               | -               | -       | -           | -       | -        | -        | -        | -         |
| 1 Internal SRAM        | -         | -         | -                         | -   | -               | X               | X       | X           | X       | X        | X        | X        | -         |
| 2 Internal ROM         | X         | -         | -                         | -   | -               | -               | -       | -           | -       | -        | -        | -        | -         |
| 3 Internal Flash       | X         | -         | -                         | X   | -               | X               | -       | -           | X       | X        | -        | -        | -         |
| 4 USB HS Dual Port RAM | -         | X         | -                         | -   | -               | -               | -       | -           | -       | -        | -        | -        | -         |

.....continued

| Hosts                                    | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |

[11.1. Embedded Memories](#)

## 19.3 Functional Description

### 19.3.1 Memory Mapping

The MATRIX provides one decoder for every AHB Host interface. The decoder offers each AHB Host several memory mappings. Each memory area may be assigned to several Clients. Thus booting at the same address while using different AHB Clients (i.e., external RAM, internal ROM or internal Flash, etc.) is possible.

The MATRIX user interface provides the Host Remap Control Register (MATRIX\_MRCR) that performs remap action for every Host independently.

### 19.3.2 Special Bus Granting Mechanism

The MATRIX provides some speculative bus granting techniques in order to anticipate access requests from Hosts. This technique reduces latency at the first access of a burst, or for a single transfer, as long as the Client is free from any other Host access. Bus granting sets a different default Host for every Client.

At the end of the current access, if no other request is pending, the Client remains connected to its associated default Host. A Client can be associated with three kinds of default Hosts:

- No default Host
- Last access Host
- Fixed default Host

To change from one type of default Host to another, the MATRIX user interface provides the Client Configuration registers, one for every Client, that set a default Host for each Client. The Client Configuration register contains the fields DEFMSTR\_TYPE and FIXED\_DEFMSTR. The 2-bit DEFMSTR\_TYPE field selects the default Host type (no default, last access Host, fixed default Host), whereas the 4-bit FIXED\_DEFMSTR field selects a fixed default Host provided that DEFMSTR\_TYPE is set to fixed default Host. Please refer to the ["Bus Matrix Client Configuration Registers"](#) section.

#### 19.3.2.1 No Default Host

After the end of the current access, if no other request is pending, the Client is disconnected from all Hosts.

This configuration incurs one latency clock cycle for the first access of a burst after bus Idle. Arbitration without default Host may be used for Hosts that perform significant bursts or several transfers with no Idle in between, or if the Client bus bandwidth is widely used by one or more Hosts.

This configuration provides no benefit on access latency or bandwidth when reaching maximum Client bus throughput whatever the number of requesting Hosts.

### 19.3.2.2 Last Access Host

After the end of the current access, if no other request is pending, the Client remains connected to the last Host that performed an access request.

This allows the MATRIX to remove the one latency cycle for the last Host that accessed the Client. Other non-privileged Hosts still get one latency clock cycle if they want to access the same Client. This technique is useful for Hosts that mainly perform single accesses or short bursts with some Idle cycles in between.

This configuration provides no benefit on access latency or bandwidth when reaching maximum Client bus throughput whatever is the number of requesting Hosts.

### 19.3.2.3 Fixed Default Host

At the end of the current access, if no other request is pending, the Client connects to its fixed default Host. Unlike the last access Host, the fixed default Host does not change unless the user modifies it by software (FIXED\_DEFMSTR field of the related MATRIX\_SCFG).

This allows the MATRIX arbiters to remove the one latency clock cycle for the fixed default Host of the Client. All requests attempted by the fixed default Host do not cause any arbitration latency, whereas other non-privileged Hosts will get one latency cycle. This technique is useful for a Host that mainly performs single accesses or short bursts with Idle cycles in between.

This configuration provides no benefit on access latency or bandwidth when reaching maximum Client bus throughput, regardless of the number of requesting Hosts.

## 19.3.3 Arbitration

The MATRIX provides an arbitration technique that reduces latency when conflicting cases occur; for example, when two or more Hosts try to access the same Client at the same time. One arbiter per AHB Client is provided, so that each Client is arbitrated differently.

The MATRIX provides the user with two arbitration types for each Client:

1. Round-robin Arbitration (default)
2. Fixed Priority Arbitration

Each algorithm may be complemented by selecting a default Host configuration for each Client.

When re-arbitration is required, specific conditions apply. Refer to the "[Arbitration Rules](#)" section.

### 19.3.3.1 Arbitration Rules

Each arbiter has the ability to arbitrate between requests from two or more Hosts. To avoid burst breaking and to provide maximum throughput for Client interfaces, arbitration should take place during the following cycles:

- Idle cycles: When a Client is not connected to any Host or is connected to a Host which is not currently accessing it
- Single cycles: When a Client is performing a single access
- End of Burst cycles: When the current cycle is the last cycle of a burst transfer. For a defined length burst, predicted end of burst matches the size of the transfer but is managed differently for undefined length burst. Refer to the "[Undefined Length Burst Arbitration](#)" section.
- Slot cycle limit: When the slot cycle counter has reached the limit value indicating that the current Host access is too long and must be broken. Refer to the "[Slot Cycle Limit Arbitration](#)" section.

#### 19.3.3.1.1 Undefined Length Burst Arbitration

In order to prevent Client handling during undefined length bursts, the user can trigger the re-arbitration before the end of the incremental bursts. The re-arbitration period can be selected from the following Undefined Length Burst Type (ULBT) possibilities:

1. Unlimited: no predetermined end of burst is generated. This value enables 1-Kbyte burst lengths.
2. 1-beat bursts: predetermined end of burst is generated at each single transfer during the INCR transfer.
3. 4-beat bursts: predetermined end of burst is generated at the end of each 4-beat boundary during INCR transfer.
4. 8-beat bursts: predetermined end of burst is generated at the end of each 8-beat boundary during INCR transfer.

5. 16-beat bursts: predetermined end of burst is generated at the end of each 16-beat boundary during INCR transfer.
6. 32-beat bursts: predetermined end of burst is generated at the end of each 32-beat boundary during INCR transfer.
7. 64-beat bursts: predetermined end of burst is generated at the end of each 64-beat boundary during INCR transfer.
8. 128-beat bursts: predetermined end of burst is generated at the end of each 128-beat boundary during INCR transfer.

The use of undefined length 16-beat bursts, or less, is discouraged since this decreases the overall bus bandwidth due to arbitration and Client latencies at each first access of a burst.

If the Host does not permanently and continuously request the same Client or has an intrinsically limited average throughput, the ULBT should be left at its default unlimited value, knowing that the AHB specification natively limits all word bursts to 256 beats and double-word bursts to 128 beats because of its 1-Kbyte address boundaries.

Unless duly needed, the ULBT should be left at its default value of 0 for power saving.

This selection is made through the ULBT field of the Host Configuration Registers (MATRIX\_MCFG).

### 19.3.3.1.2 Slot Cycle Limit Arbitration

The MATRIX contains specific logic to break long accesses, such as very long bursts on a very slow Client (e.g., an external low speed memory). At each arbitration time, a counter is loaded with the value previously written in the SLOT\_CYCLE field of the related Client Configuration Register (MATRIX\_SCFG) and decreased at each clock cycle. When the counter elapses, the arbiter has the ability to re-arbitrate at the end of the current AHB bus access cycle.

Unless a Host has a very tight access latency constraint, which could lead to data overflow or underflow due to a badly undersized internal FIFO with respect to its throughput, the Slot Cycle Limit should be disabled (SLOT\_CYCLE = 0) or set to its default maximum value in order not to inefficiently break long bursts performed by some bus Hosts.

In most cases, this feature is not needed and should be disabled for power saving.

This feature does not prevent a Client from locking its access indefinitely.

### 19.3.3.2 Arbitration Priority Scheme

The MATRIX arbitration scheme is organized in priority pools.

Round-robin priority is used in the highest and lowest priority pools, whereas fixed level priority is used between priority pools and in the intermediate priority pools.

For each Client, each Host is assigned to one of the Client priority pools through the priority registers for Clients (MxPR fields of MATRIX\_PRAS and MATRIX\_PRBS). When evaluating Host requests, this programmed priority level always takes precedence.

After reset, all the Hosts except those of the Cortex-M7 belong to the lowest priority pool (MxPR = 0) and are therefore granted bus access in a true round-robin order.

The highest priority pool must be specifically reserved for Hosts requiring very low access latency. If more than one Host belongs to this pool, they will be granted bus access in a biased round-robin manner which allows tight and deterministic maximum access latency from AHB bus requests. In the worst case, any currently occurring high-priority Host request will be granted after the current bus Host access has ended and other high priority pool Host requests, if any, have been granted once each.

The lowest priority pool shares the remaining bus bandwidth between AHB Hosts.

Intermediate priority pools allow fine priority tuning. Typically, a moderately latency-critical Host or a bandwidth-only critical Host will use such a priority level. The higher the priority level (MxPR value), the higher the Host priority.

All combinations of MxPR values are allowed for all Hosts and Clients. For example, some Hosts might be assigned the highest priority pool (round-robin), and remaining Hosts the lowest priority pool (round-robin), with no Host for intermediate fix priority levels.

If more than one Host requests the Client bus, regardless of the respective Hosts priorities, no Host will be granted the Client bus for two consecutive runs. A Host can only get back-to-back grants so long as it is the only requesting Host.

### 19.3.3.2.1 Fixed Priority Arbitration

The fixed priority arbitration algorithm is the first and only arbitration algorithm applied between Hosts from distinct priority pools. It is also used in priority pools other than the highest and lowest priority pools (intermediate priority pools).

Fixed priority arbitration is used by the MATRIX arbiters to dispatch the requests from different Hosts to the same Client by using the fixed priority defined by the user. If requests from two or more Hosts are active at the same time, the Host with the highest priority number is serviced first. If requests from two or more Hosts with the same priority are active at the same time, the Host with the highest number is serviced first.

For each Client, the priority of each Host is defined in the MxPR field in the Priority Registers, MATRIX\_PRAS and MATRIX\_PRBS.

### 19.3.3.2.2 Round-Robin Arbitration

Round-robin arbitration is only used in the highest and lowest priority pools. It allows the MATRIX arbiters to properly dispatch requests from different Hosts to the same Client. If two or more Host requests are active at the same time in the priority pool, they are serviced in a round-robin increasing Host number order.

## 19.3.4 System I/O Configuration

The System I/O Configuration register (CCFG\_SYSIO) configures I/O lines in System I/O mode (such as JTAG, ERASE, USB, etc.) or as general purpose I/O lines. Enabling or disabling the corresponding I/O lines in peripheral mode or in PIO mode (PIO\_PER or PIO\_PDR registers) in the PIO controller as no effect. However, the direction (input or output), pull-up, pull-down and other mode control is still managed by the PIO controller.

## 19.3.5 SMC NAND Flash Chip Select Configuration

The SMC Nand Flash Chip Select Configuration Register (CCFG\_SMCNFCS) manages the chip select signal (NCSx) and its assignment to NAND Flash.

Each NCSx may or may not be individually assigned to NAND Flash. When the NCSx is assigned to NAND Flash, the signals NANDOE and NANDWE are used for the NCSx signals selected.

## 19.3.6 Configuration of Automatic Clock-off Mode

To reduce power consumption, MATRIX, Bridge and EFC automatic clock gating can be enabled by writing a '1' to bits MATCKG, BRIDCKG and EFCCKG, respectively, in the Dynamic Clock Gating register (CCFG\_DYNCKG).

## 19.3.7 Register Write Protection

To prevent any single software error from corrupting MATRIX behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the [Write Protection Mode Register](#) (MATRIX\_WPMR).

If a write access to a write-protected register is detected, the WPVS flag in the [Write Protection Status Register](#) (MATRIX\_WPSR) is set and the field WPVSR indicates the register in which the write access has been attempted.

The WPVS flag is reset by writing the Bus Matrix Write Protect Mode Register (MATRIX\_WPMR) with the appropriate access key WPKEY.

The following registers can be write-protected:

- [Bus Matrix Host Configuration Registers](#)
- [Bus Matrix Client Configuration Registers](#)
- [Bus Matrix Priority Registers A For Clients](#)
- [Bus Matrix Priority Registers B For Clients](#)
- [Bus Matrix Host Remap Control Register](#)

### 19.4 Register Summary

| Offset              | Name          | Bit Pos. | 7                  | 6 | 5         | 4                 | 3 | 2               | 1         | 0 |  |
|---------------------|---------------|----------|--------------------|---|-----------|-------------------|---|-----------------|-----------|---|--|
| 0x00                | MATRIX_MCFG0  | 7:0      |                    |   |           |                   |   |                 | ULBT[2:0] |   |  |
|                     |               | 15:8     |                    |   |           |                   |   |                 |           |   |  |

### 19.4.1 Bus Matrix Host Configuration Registers

**Name:** MATRIX\_MCFGx  
**Offset:** 0x00 + x\*0x04 [x=0..12]  
**Reset:** 0x00000004  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [Write Protection Mode Register](#).

#### Bits 2:0 – ULBT[2:0] Undefined Length Burst Type

| Value | Name          | Description  |
|-------|---------------|--|
| 0     | UNLTD_LENGTH  | Unlimited Length Burst—No predicted end of burst is generated, therefore INCR bursts coming from this Host can only be broken if the Client Slot Cycle Limit is reached. If the Slot Cycle Limit is not reached, the burst is normally completed by the Host, at the latest, on the next AHB 1-Kbyte address boundary, allowing up to 256-beat word bursts or 128-beat double-word bursts.<br><br>This value should not be used in the very particular case of a Host capable of performing back-to-back undefined length bursts on a single Client, since this could indefinitely freeze the Client arbitration and thus prevent another Host from accessing this Client. |
| 1     | SINGLE_ACCESS | Single Access—The undefined length burst is treated as a succession of single accesses, allowing re-arbitration at each beat of the INCR burst or bursts sequence.   |
| 2     | 4BEAT_BURST   | 4-beat Burst—The undefined length burst or bursts sequence is split into 4-beat bursts or less, allowing re-arbitration every 4 beats.   |
| 3     | 8BEAT_BURST   | 8-beat Burst—The undefined length burst or bursts sequence is split into 8-beat bursts or less, allowing re-arbitration every 8 beats.   |
| 4     | 16BEAT_BURST  | 16-beat Burst—The undefined length burst or bursts sequence is split into 16-beat bursts or less, allowing re-arbitration every 16 beats.  |
| 5     | 32BEAT_BURST  | 32-beat Burst —The undefined length burst or bursts sequence is split into 32-beat bursts or less, allowing re-arbitration every 32 beats.   |
| 6     | 64BEAT_BURST  | 64-beat Burst—The undefined length burst or bursts sequence is split into 64-beat bursts or less, allowing re-arbitration every 64 beats.  |

# SAM E70/S70/V70/V71

## Bus Matrix (MATRIX)

| Value | Name          | Description   |
|-------|---------------|---|
| 7     | 128BEAT_BURST | 128-beat Burst—The undefined length burst or bursts sequence is split into 128-beat bursts or less, allowing re-arbitration every 128 beats.<br><b>Note:</b> Unless duly needed, the ULBT should be left at its default 0 value for power saving. |

### 19.4.2 Bus Matrix Client Configuration Registers

**Name:** MATRIX\_SCFGx  
**Offset:** 0x40 + x\*0x04 [x=0..8]  
**Reset:** 0x000201FE  
**Property:** Read/Write

For Clients 2 and 3 (x = 2,3) the default value is 0x0002\_01FF, making the default value of DEFMSTR\_TYPE = 2 (FIXED).

This register can only be written if the WPEN bit is cleared in the [Write Protection Mode Register](#).

|        |                 |     |                    |     |     |     |                   |     |  |
|--------|-----------------|-----|--------------------|-----|-----|-----|-------------------|-----|--|
| Bit    | 31              | 30  | 29                 | 28  | 27  | 26  | 25                | 24  |  |
|        |                 |     |                    |     |     |     |                   |     |  |
| Access |                 |     |                    |     |     |     |                   |     |  |
| Reset  |                 |     |                    |     |     |     |                   |     |  |
| Bit    | 23              | 22  | 21                 | 20  | 19  | 18  | 17                | 16  |  |
|        |                 |     | FIXED_DEFMSTR[3:0] |     |     |     | DEFMSTR_TYPE[1:0] |     |  |
| Access |                 |     | R/W                | R/W | R/W | R/W | R/W               | R/W |  |
| Reset  |                 |     | 0                  | 0   | 0   | 0   | 1                 | 0   |  |
| Bit    | 15              | 14  | 13                 | 12  | 11  | 10  | 9                 | 8   |  |
|        |                 |     |                    |     |     |     | SLOT_CYCLE[8:7]   |     |  |
| Access |                 |     |                    |     |     |     | R/W               | R/W |  |
| Reset  |                 |     |                    |     |     |     | 0                 | 1   |  |
| Bit    | 7               | 6   | 5                  | 4   | 3   | 2   | 1                 | 0   |  |
|        | SLOT_CYCLE[6:0] |     |                    |     |     |     |                   |     |  |
| Access | R/W             | R/W | R/W                | R/W | R/W | R/W | R/W               |     |  |
| Reset  | 1               | 1   | 1                  | 1   | 1   | 1   | 1                 |     |  |

#### Bits 21:18 – FIXED\_DEFMSTR[3:0] Fixed Default Host

Number of the Default Host for this Client. Only used if DEFMSTR\_TYPE is 2. Specifying the number of a Host which is not connected to the selected Client is equivalent to setting DEFMSTR\_TYPE to 0.

#### Bits 17:16 – DEFMSTR\_TYPE[1:0] Default Host Type

| Value | Name  | Description   |
|-------|-------|---|
| 0     | NONE  | No Default Host — At the end of the current Client access, if no other Host request is pending, the Client is disconnected from all Hosts.<br><br>This results in a one clock cycle latency for the first access of a burst transfer or for a single access.  |
| 1     | LAST  | Last Default Host — At the end of the current Client access, if no other Host request is pending, the Client stays connected to the last Host having accessed it.<br><br>This results in not having one clock cycle latency when the last Host tries to access the Client again.                                      |
| 2     | FIXED | Fixed Default Host — At the end of the current Client access, if no other Host request is pending, the Client connects to the fixed Host the number that has been written in the FIXED_DEFMSTR field.<br><br>This results in not having one clock cycle latency when the fixed Host tries to access the Client again. |

#### Bits 9:1 – SLOT\_CYCLE[8:0] Maximum Bus Grant Duration for Hosts

When SLOT\_CYCLE AHB clock cycles have elapsed since the last arbitration, a new arbitration takes place to let another Host access this Client. If another Host is requesting the Client bus, then the current Host burst is broken.

# SAM E70/S70/V70/V71

## Bus Matrix (MATRIX)

---

---

If SLOT\_CYCLE = 0, the slot cycle limit feature is disabled and bursts always complete unless broken according to the ULBT.

This limit has been placed in order to enforce arbitration so as to meet potential latency constraints of Hosts waiting for Client access.

This limit must not be too small. Unreasonably small values break every burst and the MATRIX arbitrates without performing any data transfer. The default maximum value is usually an optimal conservative choice.

In most cases, this feature is not needed and must be disabled for power saving, for additional information, refer to [“Slot Cycle Limit Arbitration”](#) .

### 19.4.3 Bus Matrix Priority Registers A For Clients

**Name:** MATRIX\_PRASx  
**Offset:** 0x80 + x\*0x08 [x=0..8]  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPE bit is cleared in the [Write Protection Mode Register](#).

|        |     |           |    |     |     |           |    |     |     |

**Bits 0:1, 4:5, 8:9, 12:13, 16:17, 20:21, 24:25, 28:29 – MxPR** Host x Priority

Fixed priority of Host x for accessing the selected Client. The higher the number, the higher the priority.

All the Hosts programmed with the same MxPR value for the Client make up a priority pool.

Round-robin arbitration is used in the lowest (MxPR = 0) and highest (MxPR = 3) priority pools.

Fixed priority is used in intermediate priority pools (MxPR = 1) and (MxPR = 2).

See [“Arbitration Priority Scheme”](#) for details.

**19.4.4 Bus Matrix Priority Registers B For Clients**

**Name:** MATRIX\_PRBSx  
**Offset:** 0x84 + x\*0x08 [x=0..8]  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPE bit is cleared in the [Write Protection Mode Register](#).

**Bits 0:1, 4:5, 8:9, 12:13, 16:17 – MxPR Host 8 Priority**

Fixed priority of Host x for accessing the selected Client. The higher the number, the higher the priority.  
 All the Hosts programmed with the same MxPR value for the Client make up a priority pool.  
 Round-robin arbitration is used in the lowest (MxPR = 0) and highest (MxPR = 3) priority pools.  
 Fixed priority is used in intermediate priority pools (MxPR = 1) and (MxPR = 2).  
 See [“Arbitration Priority Scheme”](#) for details.

### 19.4.5 Bus Matrix Host Remap Control Register

**Name:** MATRIX\_MRCR  
**Offset:** 0x0100  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [Write Protection Mode Register](#).

| Reset  |     | 0               | 0      | 0      | 0      |        |     |        |     |

**Bits 31:16 – CAN1DMABA[15:0]** CAN1 DMA Base Address  
 Give the 16-bit MSB of the CAN1 DMA base address. The 16-bit LSB must be programmed into CAN1 User interface.  
 Default address is 0x20400000.

**Bit 12 – SYSIO12** PB12 or ERASE Assignment

| Value | Description              |
|-------|--------------------------|
| 0     | ERASE function selected. |
| 1     | PB12 function selected.  |

**Bit 7 – SYSIO7** PB7 or TCK/SWCLK Assignment

| Value | Description                  |
|-------|------------------------------|
| 0     | TCK/SWCLK function selected. |
| 1     | PB7 function selected.       |

**Bit 6 – SYSIO6** PB6 or TMS/SWDIO Assignment

| Value | Description                  |
|-------|------------------------------|
| 0     | TMS/SWDIO function selected. |
| 1     | PB6 function selected.       |

**Bit 5 – SYSIO5** PB5 or TDO/TRACESWO Assignment

| Value | Description                     |
|-------|---------------------------------|
| 0     | TDO/TRACESWO function selected. |
| 1     | PB5 function selected.          |

**Bit 4 – SYSIO4** PB4 or TDI Assignment

| Value | Description            |
|-------|------------------------|
| 0     | TDI function selected. |
| 1     | PB4 function selected. |

### 19.4.8 Peripheral Clock Configuration Register

**Name:** CCFG\_PCCR  
**Offset:** 0x0118  
**Reset:** 0x00022224  
**Property:** Read/Write

**Bit 22 – I2SC1CC** I2SC1 Clock Configuration

| Value | Description                        |
|-------|------------------------------------|
| 0     | Peripheral clock of I2SC1 is used. |
| 1     | GCLK is used.                      |

**Bit 21 – I2SC0CC** I2SC0 Clock Configuration

| Value | Description                        |
|-------|------------------------------------|
| 0     | Peripheral clock of I2SC0 is used. |
| 1     | GCLK is used.                      |

**Bit 20 – TC0CC** TC0 Clock Configuration

| Value | Description             |
|-------|-------------------------|
| 0     | PCK6 is used (default). |
| 1     | PCK7 is used.           |

### 19.4.9 Dynamic Clock Gating Register

**Name:** CCFG\_DYNCKG  
**Offset:** 0x011C  
**Reset:** 0x00000007  
**Property:** Read/Write

**Note:** Clearing this register optimizes the power consumption of the system bus circuitry.

#### Bit 2 – EFCKG EFC Dynamic Clock Gating Enable

| Value | Description  |
|-------|--|
| 0     | EFC dynamic clock gating enabled. The Embedded Flash Controller circuitry is driven by the clock only when an access to the Flash memory is being performed. Power consumption is optimized. |
| 1     | EFC dynamic clock gating disabled. The Embedded Flash Controller is always driven by the clock in Active mode.   |

#### Bit 1 – BRIDCKG Bridge Dynamic Clock Gating Enable

| Value | Description  |
|-------|--|
| 0     | Bridge dynamic clock gating enabled. The peripheral bridge circuitry is driven by the clock only when a transfer to/from any peripheral located on the APB bus is being performed. Power consumption is optimized. |
| 1     | Bridge dynamic clock gating disabled. The peripheral bridge circuitry is always driven by the clock in Active mode.  |

#### Bit 0 – MATCKG MATRIX Dynamic Clock Gating

| Value | Description   |
|-------|---|
| 0     | MATRIX dynamic clock gating enabled. The MATRIX circuitry is driven by the clock only when a transfer to a peripheral is being performed. Power consumption is optimized. |
| 1     | MATRIX dynamic clock gating disabled. The MATRIX circuitry is always driven by the clock in Active mode.  |

### 19.4.10 SMC NAND Flash Chip Select Configuration Register

**Name:** CCFG\_SMCNFCS  
**Offset:** 0x0124  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bit 3 – SMC\_NFCS3 SMC NAND Flash Chip Select 3 Assignment

| Value | Description  |
|-------|--|
| 0     | NCS3 is not assigned to a NAND Flash (NANDOE and NANWE not used for NCS3). |
| 1     | NCS3 is assigned to a NAND Flash (NANDOE and NANWE used for NCS3).         |

#### Bit 2 – SMC\_NFCS2 SMC NAND Flash Chip Select 2 Assignment

| Value | Description  |
|-------|--|
| 0     | NCS2 is not assigned to a NAND Flash (NANDOE and NANWE not used for NCS2). |
| 1     | NCS2 is assigned to a NAND Flash (NANDOE and NANWE used for NCS2).         |

#### Bit 1 – SMC\_NFCS1 SMC NAND Flash Chip Select 1 Assignment

| Value | Description  |
|-------|--|
| 0     | NCS1 is not assigned to a NAND Flash (NANDOE and NANWE not used for NCS1). |
| 1     | NCS1 is assigned to a NAND Flash (NANDOE and NANWE used for NCS1).         |

#### Bit 0 – SMC\_NFCS0 SMC NAND Flash Chip Select 0 Assignment

| Value | Description  |
|-------|--|
| 0     | NCS0 is not assigned to a NAND Flash (NANDOE and NANWE not used for NCS0). |
| 1     | NCS0 is assigned to a NAND Flash (NANDOE and NANWE used for NCS0).         |

### 19.4.11 Write Protection Mode Register

**Name:** MATRIX\_WPMR  
**Offset:** 0x01E4  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |              |     |     |     |     |     |     |     |
|--------|-----|--------------|-----|-----|-----|-----|-----|-----|-----|
|        | Bit | 31           | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        |     | WPKEY[23:16] |     |     |     |     |     |     |     |
| Access |     | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        | Bit | 23           | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        |     | WPKEY[15:8]  |     |     |     |     |     |     |     |
| Access |     | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        | Bit | 15           | 14  | 13  | 12  | 11  | 10  | 9   | 8   |
|        |     | WPKEY[7:0]   |     |     |     |     |     |     |     |
| Access |     | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        | Bit | 7            | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        |     | WPEN         |     |     |     |     |     |     |     |
| Access |     |              |     |     |     |     |     |     | R/W |
| Reset  |     |              |     |     |     |     |     |     | 0   |

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

| Value    | Name   | Description   |
|----------|--------|---|
| 0x4D4154 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit.<br>Always reads as 0. |

#### Bit 0 – WPEN Write Protection Enable

Refer to the ["Register Write Protection"](#) section for the list of registers that can be write-protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x4D4154 ("MAT" in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x4D4154 ("MAT" in ASCII).  |

**19.4.12 Write Protection Status Register**

**Name:** MATRIX\_WPSR  
**Offset:** 0x01E8  
**Reset:** 0x00000000  
**Property:** Read-only

|        |     |                            |    |    |    |    |    |    |      |

| Reset  |     | 0                          | 0  | 0  | 0  | 0  | 0  | 0  | 0    |
|        |     |                            |    |    |    |    |    |    |      |
|        | Bit | 7                          | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
|        |     | [Greyed out register bits] |    |    |    |    |    |    | WPVS |
| Access |     |                            |    |    |    |    |    |    | R    |
| Reset  |     |                            |    |    |    |    |    |    | 0    |

**Bits 23:8 – WPVSR[15:0]** Write Protection Violation Source  
 When WPVS = 1, WPVSR indicates the register address offset at which a write access has been attempted.

**Bit 0 – WPVS** Write Protection Violation Status

| Value | Description   |
|-------|---|
| 0     | No write protection violation has occurred since the last write of the MATRIX_WPMR.   |
| 1     | A write protection violation has occurred since the last write of the MATRIX_WPMR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSR. |

## **20. USB Transmitter Macrocell Interface (UTMI)**

### **20.1 Description**

The USB Transmitter Macrocell Interface (UTMI) registers manage specific aspects of the integrated USB transmitter macrocell functionality not controlled in USB sections.

### **20.2 Embedded Characteristics**

- 32-bit UTMI Registers Control Product-specific Behavior

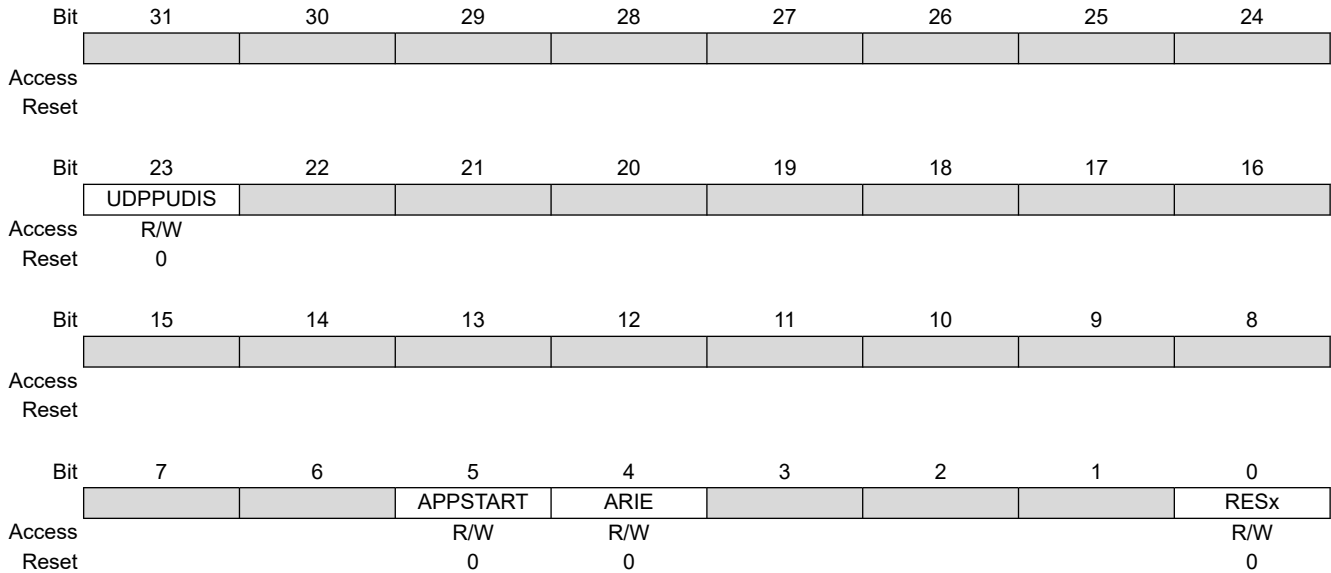

### 20.3 Register Summary

| Offset              | Name         | Bit Pos. | 7        | 6 | 5        | 4    | 3 | 2 | 1         | 0    |
|---------------------|--------------|----------|----------|---|----------|------|---|---|-----------|------|
| 0x00<br>...<br>0x0F | Reserved     |          |          |   |          |      |   |   |           |      |
| 0x10                | UTMI_OHCIICR | 7:0      |          |   | APPSTART | ARIE |   |   |           | RESx |
|                     |              | 15:8     |          |   |          |      |   |   |           |      |
|                     |              | 23:16    | UDPPUDIS |   |          |      |   |   |           |      |
|                     |              | 31:24    |          |   |          |      |   |   |           |      |
| 0x14<br>...<br>0x2F | Reserved     |          |          |   |          |      |   |   |           |      |
| 0x30                | UTMI_CKTRIM  | 7:0      |          |   |          |      |   |   | FREQ[1:0] |      |
|                     |              | 15:8     |          |   |          |      |   |   |           |      |
|                     |              | 23:16    |          |   |          |      |   |   |           |      |
|                     |              | 31:24    |          |   |          |      |   |   |           |      |

### 20.3.1 OHCI Interrupt Configuration Register

**Name:** UTMI\_OHCIICR  
**Offset:** 0x10  
**Reset:** 0x0  
**Property:** Read/Write

#### Bit 23 – UDPPUDIS USB Device Pull-up Disable

| Value | Description                                |
|-------|--|
| 0     | USB device pull-up connection is enabled.  |
| 1     | USB device pull-up connection is disabled. |

#### Bit 5 – APPSTART Reserved

| Value | Description   |
|-------|---------------|
| 0     | Must write 0. |

#### Bit 4 – ARIE OHCI Asynchronous Resume Interrupt Enable

| Value | Description         |
|-------|---------------------|
| 0     | Interrupt disabled. |
| 1     | Interrupt enabled.  |

#### Bit 0 – RESx USB PORTx Reset

| Value | Description      |
|-------|------------------|
| 0     | Resets USB port. |
| 1     | Usable USB port. |

# SAM E70/S70/V70/V71

## USB Transmitter Macrocell Interface (UTMI)

### 20.3.2 UTMI Clock Trimming Register

**Name:** UTMI\_CKTRIM  
**Offset:** 0x30  
**Reset:** 0x00010000  
**Property:** Read/Write

#### Bits 1:0 – FREQ[1:0] UTMI Reference Clock Frequency

| Value | Name   | Description            |
|-------|--------|------------------------|
| 0     | XTAL12 | 12 MHz reference clock |
| 1     | XTAL16 | 16 MHz reference clock |

## 21. Chip Identifier (CHIPID)

### 21.1 Description

Chip Identifier (CHIPID) registers are used to recognize the device and its revision. These registers provide the sizes and types of the on-chip memories, as well as the set of embedded peripherals.

Two CHIPID registers are embedded: Chip ID Register (CHIPID\_CIDR) and Chip ID Extension Register (CHIPID\_EXID). Both registers contain a hard-wired value that is read-only.

The CHIPID\_CIDR register contains the following fields:

- VERSION: Identifies the revision of the silicon
- EPROC: Indicates the embedded ARM processor
- NVPTYP and NVPSIZ: Identify the type of embedded non-volatile memory and the size
- SRAMSIZ: Indicates the size of the embedded SRAM
- ARCH: Identifies the set of embedded peripherals
- EXT: Shows the use of the extension identifier register

The CHIPID\_EXID register is device-dependent and reads 0 if CHIPID\_CIDR.EXT = 0.

### 21.2 Embedded Characteristics

- Chip ID Registers
  - Identification of the Device Revision, Sizes of the Embedded Memories, Set of Peripherals, Embedded Processor

**Table 21-1. SAM S70/SAM E70/SAM V70/SAM V71 Chip ID Registers**

## **22. Enhanced Embedded Flash Controller (EEFC)**

### **22.1 Description**

The Enhanced Embedded Flash Controller (EEFC) provides the interface of the Flash block with the 32-bit internal bus.

Its 128-bit wide memory interface increases performance. It also manages the programming, erasing, locking and unlocking sequences of the Flash using a full set of commands. One of the commands returns the embedded Flash descriptor definition that informs the system about the Flash organization, thus making the software generic.

### **22.2 Embedded Characteristics**

- Increases Performance in Thumb-2 Mode with 128-bit-wide Memory Interface up to 150 MHz
- Code Loop Optimization
- 128 Lock Bits, Each Protecting a Lock Region
- 9 General-purpose GPNVM Bits
- One-by-one Lock Bit Programming
- Commands Protected by a Keyword
- Erase the Entire Flash
- Erase by Sector
- Erase by Page
- Provides Unique Identifier
- Provides 512-byte User Signature Area
- Supports Erasing before Programming
- Locking and Unlocking Operations
- ECC Single and Multiple Error Flags Report
- Supports Read of the Calibration Bits
- Register Write Protection

### **22.3 Product Dependencies**

#### **22.3.1 Power Management**

The Enhanced Embedded Flash Controller (EEFC) is continuously clocked. The Power Management Controller has no effect on its behavior.

#### **22.3.2 Interrupt Sources**

The EEFC interrupt line is connected to the interrupt controller. Using the EEFC interrupt requires the interrupt controller to be programmed first. The EEFC interrupt is generated only if the value of EEFC\_FMR.FRDY is '1'.

### **22.4 Functional Description**

#### **22.4.1 Embedded Flash Organization**

The embedded Flash interfaces with the internal bus. The embedded Flash is composed of the following:

- One memory plane organized in several pages of the same size for the code.
- A separate 2 x 512-byte memory area which includes the unique chip identifier.
- A separate 512-byte memory area for the user signature.

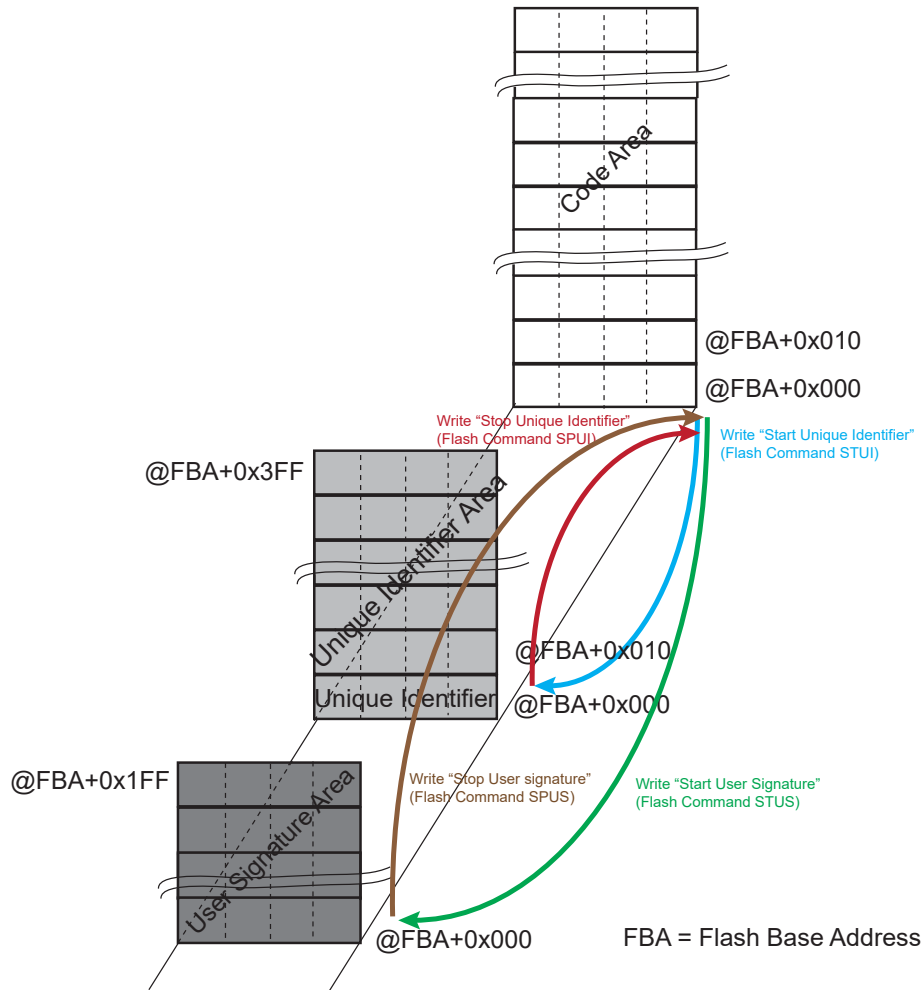

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

- Two 128-bit read buffers used for code read optimization.
- One 128-bit read buffer used for data read optimization.
- One write buffer that manages page programming. The write buffer size is equal to the page size. This buffer is write-only and accessible all along the entire flash address space, so that each word can be written to its final address.
- Several lock bits used to protect write/erase operation on several pages (lock region). A lock bit is associated with a lock region composed of several pages in the memory plane.
- Several bits that may be set and cleared through the EEFC interface, called general-purpose non-volatile memory bits (GPNVM bits).

The embedded Flash size, page size, organization of lock regions, and definition of GPNVM bits are specific to the device. The EEFC returns a descriptor of the Flash controller after a 'Get Flash Descriptor' command has been issued by the application, refer to the ["Get Flash Descriptor Command"](#).

**Figure 22-1. Flash Memory Areas**

**Figure 22-2. Organization of Embedded Flash for Code**

### 22.4.2 Read Operations

An optimized controller manages embedded Flash reads, thus increasing performance when the processor is running in Thumb-2 mode by means of the 128-bit-wide memory interface.

The Flash memory is accessible through 8-, 16- and 32-bit reads.

As the Flash block size is smaller than the address space reserved for the internal memory area, the embedded Flash wraps around the address space and appears to be repeated within it.

The read operations can be performed with or without wait states. Wait states must be programmed in the field FWS in the Flash Mode register (EEFC\_FMR). Defining FWS as 0 enables the single-cycle access of the embedded Flash. For more details, refer to the section “Electrical Characteristics” of this datasheet.

[58. Electrical Characteristics for SAM E70/S70](#)

[57. Electrical Characteristics for SAM V70/V71](#)

#### 22.4.2.1 Code Read Optimization

Code read optimization is enabled if the bit EEFC\_FMR.SCOD is cleared.

A system of 2 x 128-bit buffers is added in order to optimize sequential code fetch.

**Note:** Immediate consecutive code read accesses are not mandatory to benefit from this optimization.

The sequential code read optimization is enabled by default. If the bit EEFC\_FMR.SCOD is set, these buffers are disabled and the sequential code read is no longer optimized.

Another system of 2 x 128-bit buffers is added in order to optimize loop code fetch. Refer to the “[Code Loop Optimization](#)” section for more details.

**Figure 22-3. Code Read Optimization for FWS = 0**

**Note:** When FWS is equal to '0', all the accesses are performed in a single-cycle access.

**Figure 22-4. Code Read Optimization for FWS = 3**

**Note:** When FWS is between 1 and 3, in case of sequential reads, the first access takes (FWS + 1) cycles. The following accesses take only one cycle.

### 22.4.2.2 Code Loop Optimization

Code loop optimization is enabled when the EEFC\_FMR.CLOE bit is set.

When a backward jump is inserted in the code, the pipeline of the sequential optimization is broken and becomes inefficient. In this case, the loop code read optimization takes over from the sequential code read optimization to prevent the insertion of wait states. The loop code read optimization is enabled by default. In EEFC\_FMR, if the bit CLOE is reset to 0 or the bit SCOD is set, these buffers are disabled and the loop code read is not optimized.

When code loop optimization is enabled, if inner loop body instructions  $L_0$  to  $L_n$  are positioned from the 128-bit Flash memory cell  $M_{b0}$  to the memory cell  $M_{p1}$ , after recognition of a first backward branch, the first two Flash memory cells  $M_{b0}$  and  $M_{b1}$  targeted by this branch are cached for fast access from the processor at the next loop iteration.

Then by combining the sequential prefetch (described in the “Code Read Optimization” section) through the loop body with the fast read access to the loop entry cache, the entire loop can be iterated with no wait state.

The following figure illustrates code loop optimization.

**Figure 22-5. Code Loop Optimization**

### 22.4.2.3 Data Read Optimization

The organization of the Flash in 128 bits is associated with two 128-bit prefetch buffers and one 128-bit data read buffer, thus providing maximum system performance. This buffer is added in order to store the requested data plus all the data contained in the 128-bit aligned data. This speeds up sequential data reads if, for example, FWS is equal to 1 (see Figure 22-6). The data read optimization is enabled by default. If the bit EEFC\_FMR.SCOD is set, this buffer is disabled and the data read is no longer optimized.

**Note:** No consecutive data read accesses are mandatory to benefit from this optimization.

**Figure 22-6. Data Read Optimization for FWS = 1**

### 22.4.3 Flash Commands

The EEFC offers a set of commands to manage programming the Flash memory, locking and unlocking lock regions, consecutive programming, locking and full Flash erasing, and so on.

The commands are listed in the following table.

**Table 22-1. Set of Commands**

| Command                                 | Value | Mnemonic |
|---|-------|----------|
| Get Flash Descriptor                    | 0x00  | GETD     |
| Write Page                              | 0x01  | WP       |
| Write Page and Lock                     | 0x02  | WPL      |
| Erase Page and Write Page               | 0x03  | EWP      |
| Erase Page and Write Page and then Lock | 0x04  | EWPL     |
| Erase All                               | 0x05  | EA       |

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

| .....continued               |       |          |
|------------------------------|-------|----------|
| Command                      | Value | Mnemonic |
| Erase Pages                  | 0x07  | EPA      |
| Set Lock Bit                 | 0x08  | SLB      |
| Clear Lock Bit               | 0x09  | CLB      |
| Get Lock Bit                 | 0x0A  | GLB      |
| Set GPNVM Bit                | 0x0B  | SGPB     |
| Clear GPNVM Bit              | 0x0C  | CGPB     |
| Get GPNVM Bit                | 0x0D  | GGPB     |
| Start Read Unique Identifier | 0x0E  | STUI     |
| Stop Read Unique Identifier  | 0x0F  | SPUI     |
| Get CALIB Bit                | 0x10  | GALB     |
| Erase Sector                 | 0x11  | ES       |
| Write User Signature         | 0x12  | WUS      |
| Erase User Signature         | 0x13  | EUS      |
| Start Read User Signature    | 0x14  | STUS     |
| Stop Read User Signature     | 0x15  | SPUS     |

To execute one of these commands, select the required command using the FCMD field in the Flash Command register (EEFC\_FCR). As soon as EEFC\_FCR is written, the FRDY flag and the FVALUE field in the Flash Result register (EEFC\_FRR) are automatically cleared. Once the current command has completed, the FRDY flag is automatically set. If an interrupt has been enabled by setting the bit EEFC\_FMR.FRDY, the corresponding interrupt line of the interrupt controller is activated (This is true for all commands except for the STUI command. The FRDY flag is not set when the STUI command has completed).

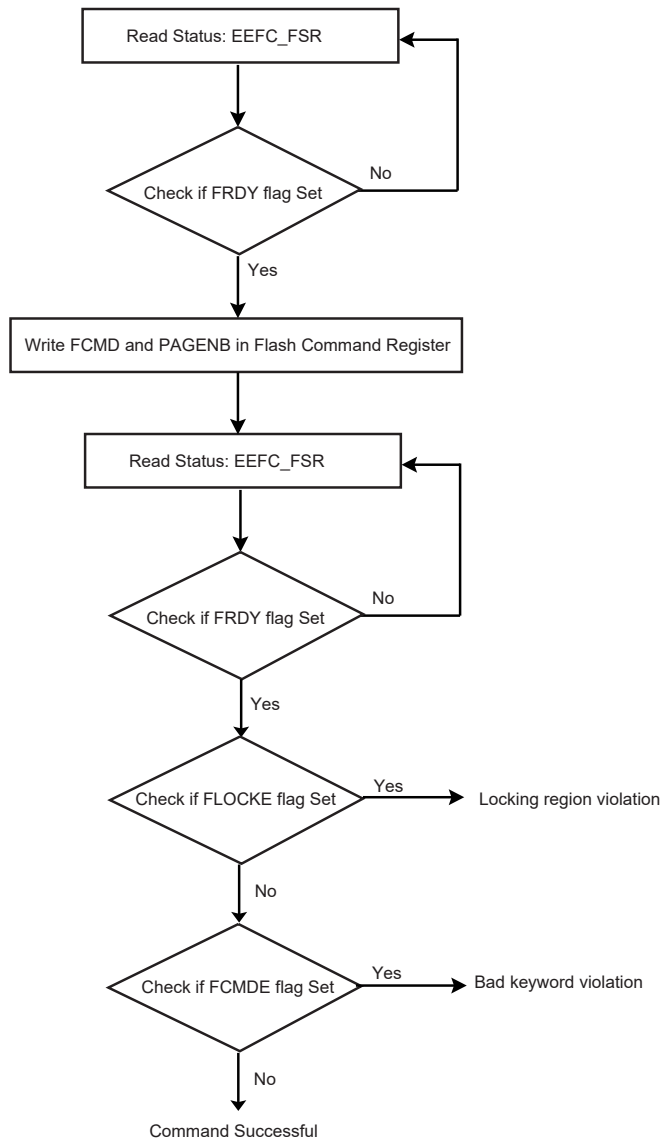

All the commands are protected by the same keyword, which must be written in the eight highest bits of EEFC\_FCR.

Writing EEFC\_FCR with data that does not contain the correct key and/or with an invalid command has no effect on the whole memory plane, but the FCMDE flag is set in the Flash Status register (EEFC\_FSR). This flag is automatically cleared by a read access to EEFC\_FSR.

When the current command writes or erases a page in a locked region, the command has no effect on the whole memory plane, but the FLOCKE flag is set in EEFC\_FSR. This flag is automatically cleared by a read access to EEFC\_FSR.

**Figure 22-7. Command State Chart**

### 22.4.3.1 Get Flash Descriptor Command

This command provides the system with information on the Flash organization. The system can take full advantage of this information. For instance, a device could be replaced by one with more Flash capacity, and so the software is able to adapt itself to the new configuration.

To get the embedded Flash descriptor, the application writes the GETD command in EEFC\_FCR. The first word of the descriptor can be read by the software application in EEFC\_FRR as soon as the FRDY flag in EEFC\_FSR rises. The next reads of EEFC\_FRR provide the following word of the descriptor. If extra read operations to EEFC\_FRR are done after the last word of the descriptor has been returned, the EEFC\_FRR value is 0 until the next valid command.

**Table 22-2. Flash Descriptor Definition**

| Symbol       | Word Index | Description                 |
|--------------|------------|-----------------------------|
| FL_ID        | 0          | Flash interface description |
| FL_SIZE      | 1          | Flash size in bytes         |
| FL_PAGE_SIZE | 2          | Page size in bytes          |

| .....continued |                     |  |
|----------------|---------------------|--|
| Symbol         | Word Index          | Description  |
| FL_NB_PLANE    | 3                   | Number of planes   |
| FL_PLANE[0]    | 4                   | Number of bytes in the plane   |
| FL_NB_LOCK     | 4 + FL_NB_PLANE     | Number of lock bits. A bit is associated with a lock region. A lock bit is used to prevent write or erase operations in the lock region. |
| FL_LOCK[0]     | 4 + FL_NB_PLANE + 1 | Number of bytes in the first lock region   |

### 22.4.3.2 Write Commands

DMA write accesses must be 32-bit aligned. If a single byte has to be written in a 32-bit word, the rest of the word must be written with ones.

Several commands are used to program the Flash.

Only '0' values can be programmed using Flash technology; '1' is the erased value. In order to program words in a page, the page must first be erased. Commands are available to erase the entire Flash or a given number of pages. With the EWP and EWPL commands, a page erase is done automatically before a page programming.

After programming, the page (the entire lock region) can be locked to prevent miscellaneous write or erase sequences. The lock bit can be automatically set after page programming using WPL or EWPL commands.

Data to be programmed in the Flash must be written in an internal latch buffer before writing the programming command in EEFC\_FCR. Data can be written at their final destination address, as the latch buffer is mapped into the Flash memory address space and wraps around within this Flash address space.

Byte and half-word AHB accesses to the latch buffer are not allowed. Only 32-bit word accesses are supported.

32-bit words must be written continuously in either ascending or descending order. Writing the latch buffer in a random order is not permitted. This prevents mapping a C-code structure to the latch buffer and accessing the data of the structure in any order. It is instead recommended to fill in a C-code structure in SRAM and copy it in the latch buffer in a continuous order.

Write operations in the latch buffer are performed with the number of wait states programmed for reading the Flash.

The latch buffer is automatically re-initialized, that is, written with logical '1', after execution of each programming command.

The programming sequence is as follows:

1. Write the data to be programmed in the latch buffer.
2. Write the programming command in EEFC\_FCR. This automatically clears the EEFC\_FSR.FRDY bit.
3. When Flash programming is completed, the EEFC\_FSR.FRDY bit rises. If an interrupt has been enabled by setting the EEFC\_FMR.FRDY bit, the interrupt line of the EEFC is activated.

Three errors can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Lock Error: The page to be programmed belongs to a locked region. A command must be run previously to unlock the corresponding region.
- Flash Error: When programming is completed, the WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

Only one page can be programmed at a time. It is possible to program all the bits of a page (full page programming) or only some of the bits of the page (partial page programming).

Depending on the number of bits to be programmed within the page, the EEFC adapts the write operations required to program the Flash.

When a 'Write Page' (WP) command is issued, the EEFC starts the programming sequence and all the bits written at '0' in the latch buffer are cleared in the Flash memory array.

During programming, that is, until EEFC\_FSR.FDRY rises, access to the Flash is not allowed.

### 22.4.3.2.1 Full Page Programming

To program a full page, all the bits of the page must be erased before writing the latch buffer and issuing the WP command. The latch buffer must be written in ascending order, starting from the first address of the page. See [Figure 22-8](#).

### 22.4.3.2.2 Partial Page Programming

To program only part of a page using the WP command, the following constraints must be respected:

- Data to be programmed must be contained in integer multiples of 128-bit address-aligned words.
- 128-bit words can be programmed only if all the corresponding bits in the Flash array are erased (at logical value '1').

See [22.4.3.2.4. Programming Bytes](#).

### 22.4.3.2.3 Optimized Partial Page Programming

The EEFC automatically detects the number of 128-bit words to be programmed. If only one 128-bit aligned word is to be programmed in the Flash array, the process is optimized to reduce the time needed for programming.

If several 128-bit words are to be programmed, a standard page programming operation is performed.

See [Figure 22-10](#).

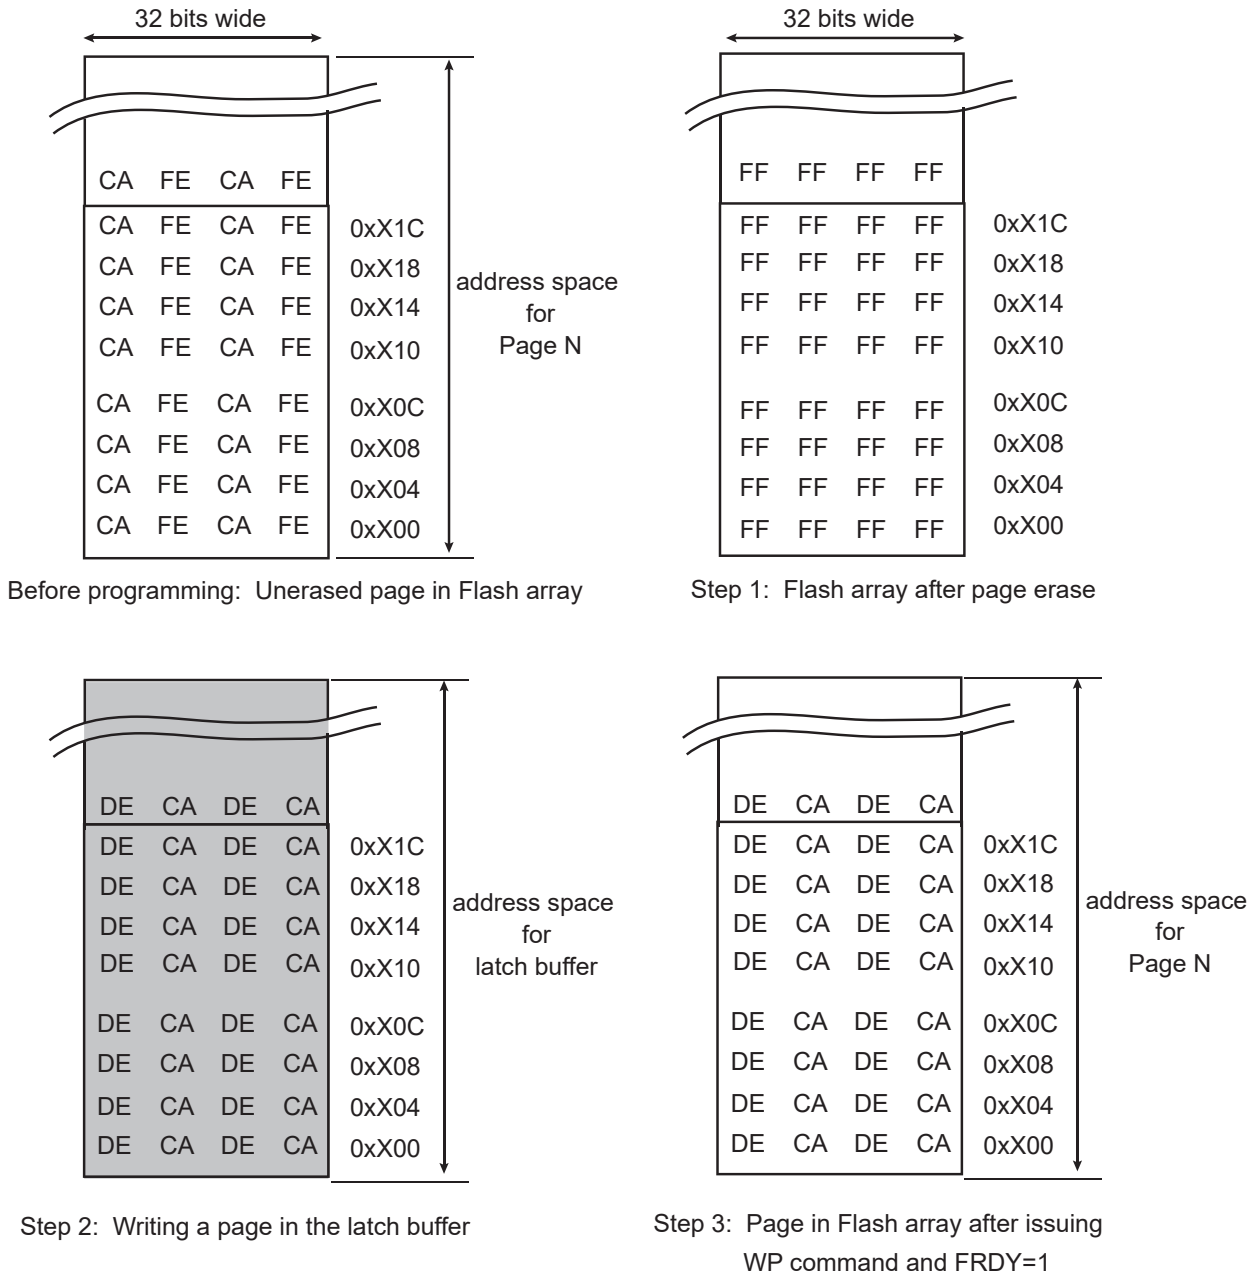

### 22.4.3.2.4 Programming Bytes

Individual bytes can be programmed using the Partial Page Programming mode.

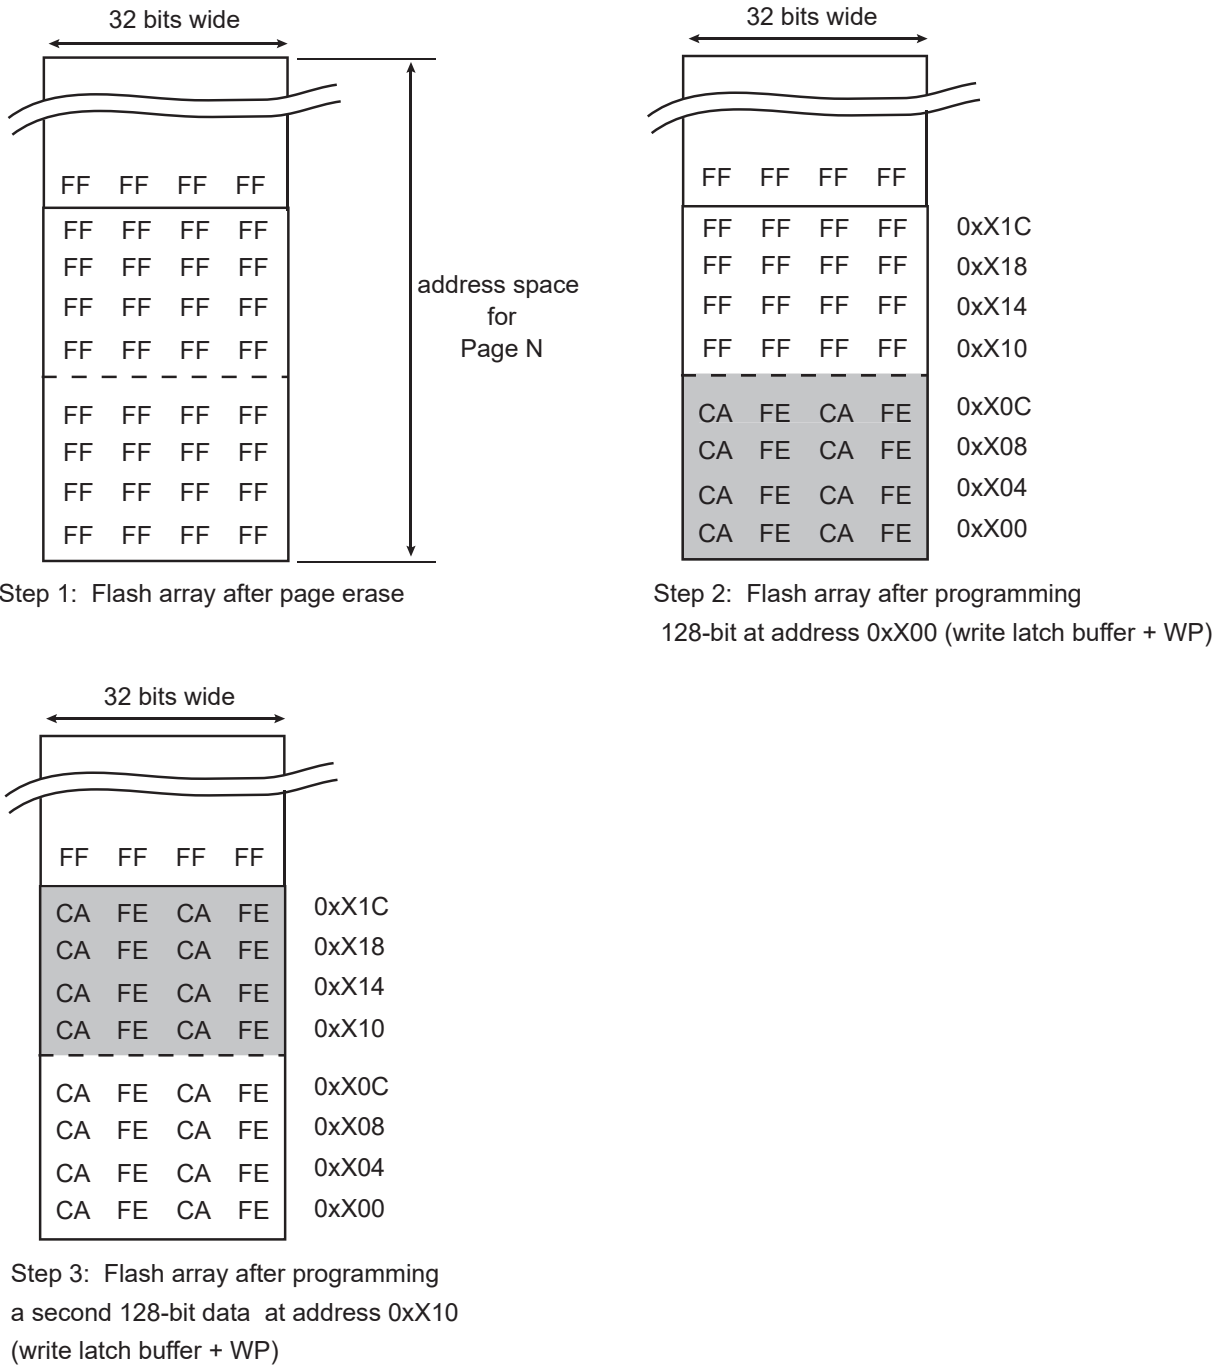

In this case, an area of 128 bits must be reserved for each byte.

Refer to the [Figure 22-11](#)

**Figure 22-8. Full Page Programming**

**Figure 22-9. Partial Page Programming**

**Figure 22-10. Optimized Partial Page Programming**

Case 1: 2 x 32 bits modified, not crossing 128-bit boundary  
 User programs WP, Flash Controller sends Write Word  
 => Only 1 word programmed => programming period reduced

Case 2: 2 x 32 bits modified, not crossing 128-bit boundary  
 User programs WP, Flash Controller sends Write Word  
 => Only 1 word programmed => programming period reduced

Case 3: 4 x 32 bits modified across 128-bit boundary  
 User programs WP, Flash Controller sends WP  
 => Whole page programmed

Case 4: 4 x 32 bits modified, not crossing 128-bit boundary  
 User programs WP, Flash Controller sends Write Word  
 => Only 1 word programmed => programming period reduced

**Figure 22-11. Programming Bytes in the Flash**

Note: The byte location shown here is for example only, it can be any byte location within a 64-bit word

### 22.4.3.3 Erase Commands

Erase commands are allowed only on unlocked regions. Depending on the Flash memory, several commands can be used to erase the Flash:

- Erase All Memory (EA): All memory is erased. The processor must not fetch code from the Flash memory.
- Erase Pages (EPA): 4, 8, 16, or 32 pages are erased in the Flash sector selected. The first page to be erased is specified in the FARG[15:2] field of the EEFC\_FCR. The first page number must be a multiple of 8, 16, or 32 depending on the number of pages to erase simultaneously.
- Erase Sector (ES): A full memory sector is erased. Sector size depends on the Flash memory. EEFC\_FCR.FARG must be set with a page number that is in the sector to be erased.

**Note:** If one sub-sector is locked within the first sector, the Erase Sector (ES) command cannot be processed on non-locked sub-sectors of the first sector. All the lock bits of the first sector must be cleared prior to issuing an ES command on the first sector. After the ES command has been issued, the first sector lock bits must be reverted to the state before clearing them.

If the processor is fetching code from the Flash memory while the EPA or ES command is being executed, the processor accesses are stalled until the EPA command is completed. To avoid stalling the processor, the code can be run out of internal SRAM.

The following are the erase sequence:

1. Erase starts immediately one of the erase commands and the FARG field are written in EEFC\_FCR. For the EPA command, the two lowest bits of the FARG field define the number of pages to be erased (FARG[1:0]), see table below.

**Table 22-3. EEFC\_FCR.FARG Field for EPA Command**

| FARG[1:0] | Number of pages to be erased with EPA command |
|-----------|---|
| 0         | 4 pages (only valid for small 8-KB sectors)   |
| 1         | 8 pages (only valid for small 8-KB sectors)   |
| 2         | 16 pages                                      |

| .....continued |   |
|----------------|---|
| FARG[1:0]      | Number of pages to be erased with EPA command |
| 3              | 32 pages (not valid for small 8-KB sectors)   |

2. When erasing is completed, the EEFC\_FSR.FRDY bit rises. If an interrupt has been enabled by setting the EEFC\_FMR.FRDY bit, the interrupt line of the interrupt controller is activated.

Three errors can be detected in EEFC\_FSR after an erasing sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Lock Error: At least one page to be erased belongs to a locked region. The erase command has been refused, no page has been erased. A command must be run previously to unlock the corresponding region.
- Flash Error: At the end of the erase period, the EraseVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

#### 22.4.3.4 Lock Bit Protection

Lock bits are associated with several pages in the embedded Flash memory plane. This defines lock regions in the embedded Flash memory plane. They prevent writing/erasing protected pages.

The following are lock sequence:

1. Execute the 'Set Lock Bit' command by writing the EEFC\_FCR.FCMD bit with the SLB command and EEFC\_FCR.FARG with a page number to be protected.
2. When the locking completes, the EEFC\_FSR.FRDY bit rises. If an interrupt has been enabled by setting the bit EEFC\_FMR.FRDY, the interrupt line of the interrupt controller is activated.
3. The result of the SLB command can be checked running a 'Get Lock Bit' (GLB) command.  
**Note:** The value of the FARG argument passed together with SLB command must not exceed the higher lock bit index available in the product.

The following two errors can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the EraseVerify or WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

It is possible to clear lock bits previously set. After the lock bits are cleared, the locked region can be erased or programmed. The unlock sequence is the following:

1. Execute the 'Clear Lock Bit' command by writing the EEFC\_FCR.FCMD bit with the CLB command and the EEFC\_FCR.FARG bit with a page number to be unprotected.
2. When the unlock completes, the EEFC\_FSR.FRDY bit rises. If an interrupt has been enabled by setting the EEFC\_FMR.FRDY bit, the interrupt line of the interrupt controller is activated.  
**Note:** The value of the FARG argument passed together with CLB command must not exceed the higher lock bit index available in the product.

Two errors can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the EraseVerify or WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

The status of lock bits can be returned by the EEFC. The 'Get Lock Bit' sequence is the following:

1. Execute the 'Get Lock Bit' command by writing EEFC\_FCR.FCMD with the GLB command. Field EEFC\_FCR.FARG is meaningless.
2. Lock bits can be read by the software application in EEFC\_FRR. The first word read corresponds to the 32 first lock bits, next reads providing the next 32 lock bits as long as it is meaningful. Extra reads to EEFC\_FRR return 0.

For example, if the third bit of the first word read in EEFC\_FRR is set, the third lock region is locked.

Two errors can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the EraseVerify or WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

**Note:** Access to the Flash in read is permitted when a 'Set Lock Bit', 'Clear Lock Bit' or 'Get Lock Bit' command is executed.

### 22.4.3.5 GPNVM Bit

The GPNVM bits do not interfere with the embedded Flash memory plane. For more details, refer to the ["Memories"](#) chapter.

The 'Set GPNVM Bit' sequence is the following:

1. Execute the 'Set GPNVM Bit' command by writing EEFC\_FCR.FCMD with the SGPB command and EEFC\_FCR.FARG with the number of GPNVM bits to be set.
2. When the GPNVM bit is set, the bit EEFC\_FSR.FRDI rises. If an interrupt was enabled by setting the bit EEFC\_FMR.FRDI, the interrupt line of the interrupt controller is activated.
3. The result of the SGPB command can be checked by running a 'Get GPNVM Bit' (GGPB) command.

**Note:** The value of the FARG argument passed together with SGPB command must not exceed the higher GPNVM index available in the product. Flash data content is not altered if FARG exceeds the limit. Command Error is detected only if FARG is greater than 8.

Two errors can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the EraseVerify or WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

It is possible to clear GPNVM bits previously set. The 'Clear GPNVM Bit' sequence is the following:

1. Execute the 'Clear GPNVM Bit' command by writing EEFC\_FCR.FCMD with the CGPB command and EEFC\_FCR.FARG with the number of GPNVM bits to be cleared.
2. When the clear completes, the bit EEFC\_FSR.FRDI rises. If an interrupt has been enabled by setting the bit EEFC\_FMR.FRDI, the interrupt line of the interrupt controller is activated.

**Note:** The value of the FARG argument passed together with CGPB command must not exceed the higher GPNVM index available in the product. Flash data content is not altered if FARG exceeds the limit. Command Error is detected only if FARG is greater than 8.

Two errors can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the EraseVerify or WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare both programmed and expected values. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

The status of GPNVM bits can be returned by the EEFC. The sequence is the following:

1. Execute the 'Get GPNVM Bit' command by writing EEFC\_FCR.FCMD with the GGPB command. Field EEFC\_FCR.FARG is meaningless.
2. GPNVM bits can be read by the software application in EEFC\_FRR. The first word read corresponds to the 32 first GPNVM bits, following reads provide the next 32 GPNVM bits as long as it is meaningful. Extra reads to EEFC\_FRR return 0.

For example, if the third bit of the first word read in EEFC\_FRR is set, the third GPNVM bit is active.

One error can be detected in EEFC\_FSR after a programming sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.

**Note:** Access to the Flash in read is permitted when a 'Set GPNVM Bit', 'Clear GPNVM Bit' or 'Get GPNVM Bit' command is executed.

### Related Links

[11. Memories](#)

#### 22.4.3.6 Calibration Bit

Calibration bits do not interfere with the embedded Flash memory plane.

The calibration bits cannot be modified.

The status of calibration bits are returned by the EEFC. The sequence is as follows:

1. Execute the 'Get CALIB Bit' command by writing EEFC\_FCR.FCMD with the GCALB command. Field EEFC\_FCR.FARG is meaningless.
2. Calibration bits can be read by the software application in EEFC\_FRR. The first word read corresponds to the first 32 calibration bits. The following reads provide the next 32 calibration bits as long as it is meaningful. Extra reads to EEFC\_FRR return 0.

The 8/12 MHz internal RC oscillator is calibrated in production. This calibration can be read through the GCALB command. [Table 22-4](#) shows the bit implementation.

The RC calibration for the 4 MHz is set to '1000000'.

**Table 22-4. Calibration Bit Indexes**

| Description                  | EEFC_FRR Bits |
|------------------------------|---------------|
| 8 MHz RC calibration output  | [28–22]       |
| 12 MHz RC calibration output | [38–32]       |

#### 22.4.3.7 Security Bit Protection

When the security bit is enabled, the Embedded Trace Macrocell (ETM) is disabled and access to the Flash through the SWD interface or through the Fast Flash Programming interface is forbidden. This ensures the confidentiality of the code programmed in the Flash.

The security bit is GPNVM0.

Disabling the security bit can only be achieved by asserting the ERASE signal at '1', and after a full Flash erase is performed. When the security bit is deactivated, all accesses to the Flash are permitted.

#### 22.4.3.8 Unique Identifier Area

Each device is programmed with a 128-bit unique identifier area .

See "[Flash Memory Areas](#)".

The sequence to read the unique identifier area is the following:

1. Execute the 'Start Read Unique Identifier' command by writing EEFC\_FCR.FCMD with the STUI command. Field EEFC\_FCR.FARG is meaningless.
2. Wait until the bit EEFC\_FSR.FRDI falls to read the unique identifier area. The unique identifier field is located in the first 128 bits of the Flash memory mapping. The 'Start Read Unique Identifier' command reuses some

addresses of the memory plane for code, but the unique identifier area is physically different from the memory plane for code.

3. To stop reading the unique identifier area, execute the 'Stop Read Unique Identifier' command by writing EEFC\_FCR.FCMD with the SPUI command. Field EEFC\_FCR.FARG is meaningless.
4. When the SPUI command has been executed, the bit EEFC\_FSR.FRDY rises. If an interrupt was enabled by setting the bit EEFC\_FMR.FRDY, the interrupt line of the interrupt controller is activated.

**Note:** During the sequence, the software cannot be fetched from the Flash.

### 22.4.3.9 User Signature Area

Each product contains a user signature area of 512 bytes. It can be used for storage. Read, write, and erase of this area is allowed. Refer to "[Flash Memory Areas](#)".

The sequence to read the user signature area is as follows:

1. Execute the 'Start Read User Signature' command by writing EEFC\_FCR.FCMD with the STUS command. Field EEFC\_FCR.FARG is meaningless.
2. Wait until the EEFC\_FSR.FRDY bit falls to read the user signature area. The user signature area is located in the first 512 bytes of the Flash memory mapping. The 'Start Read User Signature' command reuses some addresses of the memory plane but the user signature area is physically different from the memory plane
3. To stop reading the user signature area, execute the 'Stop Read User Signature' command by writing EEFC\_FCR.FCMD with the SPUS command. Field EEFC\_FCR.FARG is meaningless.
4. When the SPUI command has been executed, the bit EEFC\_FSR.FRDY rises. If an interrupt was enabled by setting the bit EEFC\_FMR.FRDY, the interrupt line of the interrupt controller is activated.

**Note:** During the sequence, the software cannot be fetched from the Flash or from the second plane in case of dual plane.

One error can be detected in EEFC\_FSR after this sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.

The sequence to write the user signature area is as follows:

1. Write the full page, at any page address, within the internal memory area address space.
2. Execute the 'Write User Signature' command by writing EEFC\_FCR.FCMD with the WUS command. Field EEFC\_FCR.FARG is meaningless.
3. When programming is completed, the EEFC\_FSR.FRDY bit rises. If an interrupt has been enabled by setting the EEFC\_FMR.FRDY bit, the corresponding interrupt line of the interrupt controller is activated.

The following two errors can be detected in EEFC\_FSR after this sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the WriteVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare what is programmed with what is expected. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

The sequence to erase the user signature area is as follows:

1. Execute the 'Erase User Signature' command by writing EEFC\_FCR.FCMD with the EUS command. Field EEFC\_FCR.FARG is meaningless.
2. When programming is completed, the EEFC\_FSR.FRDY bit rises. If an interrupt has been enabled by setting the EEFC\_FMR.FRDY bit, the corresponding interrupt line of the interrupt controller is activated.

Two errors can be detected in EEFC\_FSR after this sequence:

- Command Error: A bad keyword has been written in EEFC\_FCR.
- Flash Error: At the end of the programming, the EraseVerify test of the Flash memory has failed. After a first programming pulse, a Verify is applied. The memory is read, to compare what is programmed with what is expected. If that comparison fails, a second programming pulse is applied, and so on, until a maximum pulse number is reached. At this time, if the memory is still not containing what is expected, the FLERR flag is set high.

### 22.4.3.10 ECC Errors and Corrections

The Flash embeds an ECC module able to correct one unique error and able to detect two errors. The errors are detected while a read access is performed into memory array and stored in EEFC\_FSR (see [“EEFC Flash Status Register”](#)). The error report is kept until EEFC\_FSR is read.

There is one flag for a unique error on lower half part of the Flash word (64 LSB) and one flag for the upper half part (MSB). The multiple errors are reported in the same way.

Due to the anticipation technique to improve bandwidth throughput on instruction fetch, a reported error can be located in the next sequential Flash word compared to the location of the instruction being executed, which is located in the previously fetched Flash word.

If a software routine processes the error detection independently from the main software routine, the entire Flash located software must be rewritten because there is no storage of the error location.

If only a software routine is running to program and check pages by reading EEFC\_FSR, the situation differs from the previous case. Performing a check for ECC unique errors just after page programming completion involves a read of the newly programmed page. This read sequence is viewed as data accesses and is not optimized by the Flash controller. Thus, in case of unique error, only the current page must be reprogrammed.

### 22.4.4 Register Write Protection

To prevent any single software error from corrupting EEFC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the [“EEFC Write Protection Mode Register”](#) (EEFC\_WPMR).

The following register can be write-protected:

- [“EEFC Flash Mode Register”](#)

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

### 22.5 Register Summary

| Offset              | Name      | Bit Pos. | 7             | 6 | 5 | 4 | 3        | 2       | 1       | 0       |  |
|---------------------|-----------|----------|---------------|---|---|---|----------|---------|---------|---------|--|
| 0x00                | EEFC_FMR  | 7:0      |               |   |   |   |          |         |         | FRDY    |  |
|                     |           | 15:8     |               |   |   |   | FWS[3:0] |         |         |         |  |

|                     |           | 31:24    | WPKEY[23:16]  |   |   |   |          |         |         |         |  |

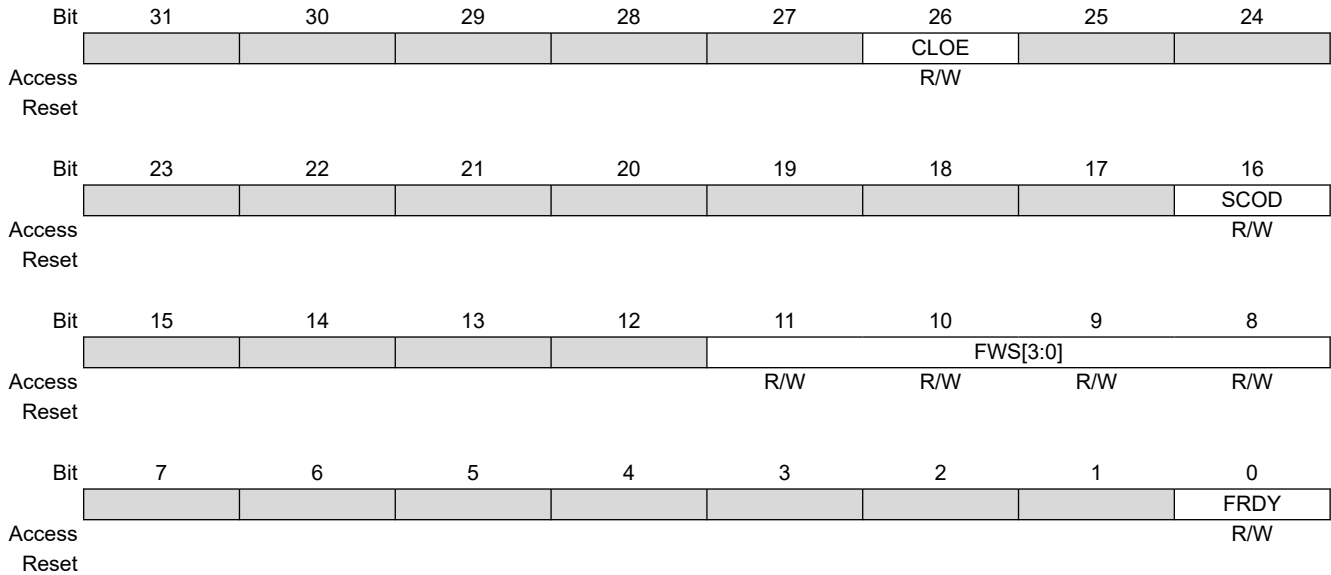

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

### 22.5.1 EEFC Flash Mode Register

**Name:** EEFC\_FMR  
**Offset:** 0x00  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the “EEFC Write Protection Mode Register” .

**Bit 26 – CLOE** Code Loop Optimization Enable

No Flash read should be done during change of this field.

| Value | Description                               |
|-------|---|
| 0     | The opcode loop optimization is disabled. |
| 1     | The opcode loop optimization is enabled.  |

**Bit 16 – SCOD** Sequential Code Optimization Disable

No Flash read should be done during change of this field.

| Value | Description                                   |
|-------|---|
| 0     | The sequential code optimization is enabled.  |
| 1     | The sequential code optimization is disabled. |

**Bits 11:8 – FWS[3:0]** Flash Wait State

This field defines the number of wait states for read and write operations:

FWS = Number of cycles for Read/Write operations - 1

**Bit 0 – FRDY** Flash Ready Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | Flash ready does not generate an interrupt.                   |
| 1     | Flash ready (to accept a new command) generates an interrupt. |

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

### 22.5.2 EEFC Flash Command Register

**Name:** EEFC\_FCR  
**Offset:** 0x04  
**Reset:** –  
**Property:** Write-only

|        |     |            |    |    |    |    |    |    |    |
|--------|-----|------------|----|----|----|----|----|----|----|
|        | Bit | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |     | FKEY[7:0]  |    |    |    |    |    |    |    |
| Access |     | W          | W  | W  | W  | W  | W  | W  | W  |

## Enhanced Embedded Flash Controller (EEFC)

### 22.5.3 EEFC Flash Status Register

**Name:** EEFC\_FSR  
**Offset:** 0x08  
**Property:** Read-only

**Bit 19 – MECCEMSB** Multiple ECC Error on MSB Part of the Memory Flash Data Bus (cleared on read)

| Value | Description   |
|-------|---|
| 0     | No multiple error detected on 64 MSB part of the Flash memory data bus since the last read of EEFC_FSR.                 |
| 1     | Multiple errors detected and NOT corrected on 64 MSB part of the Flash memory data bus since the last read of EEFC_FSR. |

**Bit 18 – UECCEMSB** Unique ECC Error on MSB Part of the Memory Flash Data Bus (cleared on read)

| Value | Description   |
|-------|---|
| 0     | No unique error detected on 64 MSB data bus of the Flash memory since the last read of EEFC_FSR.                |
| 1     | One unique error detected but corrected on 64 MSB data bus of the Flash memory since the last read of EEFC_FSR. |

**Bit 17 – MECCELSB** Multiple ECC Error on LSB Part of the Memory Flash Data Bus (cleared on read)

| Value | Description   |
|-------|---|
| 0     | No multiple error detected on 64 LSB part of the Flash memory data bus since the last read of EEFC_FSR.                 |
| 1     | Multiple errors detected and NOT corrected on 64 LSB part of the Flash memory data bus since the last read of EEFC_FSR. |

**Bit 16 – UECCELSB** Unique ECC Error on LSB Part of the Memory Flash Data Bus (cleared on read)

| Value | Description   |
|-------|---|
| 0     | No unique error detected on 64 LSB data bus of the Flash memory since the last read of EEFC_FSR.                |
| 1     | One unique error detected but corrected on 64 LSB data bus of the Flash memory since the last read of EEFC_FSR. |

**Bit 3 – FLERR** Flash Error Status (cleared when a programming operation starts)

| Value | Description  |
|-------|--|
| 0     | No Flash memory error occurred at the end of programming (EraseVerify or WriteVerify test has passed). |

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

| Value | Description   |
|-------|---|
| 1     | A Flash memory error occurred at the end of programming (EraseVerify or WriteVerify test has failed). |

### Bit 2 – FLOCKE Flash Lock Error Status (cleared on read)

This flag is automatically cleared when EEFC\_FSR is read or EEFC\_FCR is written.

| Value | Description  |
|-------|--|
| 0     | No programming/erase of at least one locked region has happened since the last read of EEFC_FSR. |
| 1     | Programming/erase of at least one locked region has happened since the last read of EEFC_FSR.    |

### Bit 1 – FCMDE Flash Command Error Status (cleared on read or by writing EEFC\_FCR)

| Value | Description   |
|-------|---|
| 0     | No invalid commands and no bad keywords were written in EEFC_FMR.     |
| 1     | An invalid command and/or a bad keyword was/were written in EEFC_FMR. |

### Bit 0 – FRDY Flash Ready Status (cleared when Flash is busy)

When set, this flag triggers an interrupt if the FRDY flag is set in EEFC\_FMR.

This flag is automatically cleared when the EEFC is busy.

| Value | Description                               |
|-------|---|
| 0     | The EEFC is busy.                         |
| 1     | The EEFC is ready to start a new command. |

### 22.5.4 EEFC Flash Result Register

**Name:** EEFC\_FRR  
**Offset:** 0x0C  
**Property:** Read-only

| Access |     | R             | R  | R  | R  | R  | R  | R  | R  |
| Reset  |     |               |    |    |    |    |    |    |    |

**Bits 31:0 – FVALUE[31:0]** Flash Result Value

The result of a Flash command is returned in this register. If the size of the result is greater than 32 bits, the next resulting value is accessible at the next register read.

# SAM E70/S70/V70/V71

## Enhanced Embedded Flash Controller (EEFC)

### 22.5.5 EEFC Write Protection Mode Register

**Name:** EEFC\_WPMR  
**Offset:** 0xE4  
**Property:** Read/Write

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

See [“Register Write Protection”](#) for the list of registers that can be protected.

| Value    | Name   | Description   |
|----------|--------|---|
| 0x454643 | PASSWD | Writing any other value in this field aborts the write operation.<br>Always reads as 0. |

#### Bit 0 – WPEN Write Protection Enable

See [“Register Write Protection”](#) for the list of registers that can be protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x454643 (EFC in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x454643 (EFC in ASCII).  |

## **23. Supply Controller (SUPC)**

### **23.1 Description**

The Supply Controller (SUPC) controls the supply voltages of the system and manages the Backup mode. In this mode, current consumption is reduced to a few microamps for backup power retention. Exit from this mode is possible on multiple wakeup sources. The SUPC also generates the slow clock by selecting either the slow RC oscillator or the 32.768 kHz crystal oscillator.

### **23.2 Embedded Characteristics**

- Management of the Core Power Supply VDDCORE and Backup Mode via the Embedded Voltage Regulator
- Supply Monitor Detection on VDDIO or a Brownout Detection on VDDCORE Triggers a Core Reset
- Generates the Slow Clock SLCK by selecting either the 22-42 kHz Slow RC Oscillator or the 32.768 kHz Crystal Oscillator
- Backup SRAM
- Low-power Tamper Detection on Two Inputs
- Anti-tampering by Immediate Clear of the General-purpose Backup Registers
- Support of Multiple Wakeup Sources for Exit from Backup Mode
  - 14 Wakeup Inputs with Programmable Debouncing
  - Real-Time Clock Alarm
  - Real-Time Timer Alarm
  - Supply Monitor Detection on VDDIO, with Programmable Scan Period and Voltage Threshold

**23.3 Block Diagram**

Figure 23-1. Supply Controller Block Diagram

## 23.4 Functional Description

### 23.4.1 Overview

The device is divided into two power supply areas:

- VDDIO power supply: includes the Supply Controller, part of the Reset Controller, the slow clock switch, the general-purpose backup registers, the supply monitor and the clock which includes the Real-time Timer and the Real-time Clock.
- Core power supply: includes part of the Reset Controller, the Brownout Detector, the processor, the SRAM memory, the Flash memory and the peripherals.

The Supply Controller (SUPC) controls the supply voltage of the core power supply. The SUPC intervenes when the VDDIO power supply rises (when the system is starting) or when Backup mode is entered.

The SUPC also integrates the slow clock generator, which is based on a 32.768 kHz crystal oscillator, and a slow RC oscillator. The slow clock defaults to the slow RC oscillator, but the software can enable the 32.768 kHz crystal oscillator and select it as the slow clock source.

The SUPC and the VDDIO power supply have a reset circuitry based on a zero-power power-on reset cell. The zero-power power-on reset allows the SUPC to start correctly as soon as the VDDIO voltage becomes valid.

At startup of the system, once the backup voltage VDDIO is valid and the slow RC oscillator is stabilized, the SUPC starts up the core by sequentially enabling the internal voltage regulator. The SUPC waits until the core voltage VDDCORE is valid, then releases the reset signal of the core `vddcore_nreset` signal.

Once the system has started, the user should program a supply monitor and/or a brownout detector. If the supply monitor detects a voltage level on VDDIO that is too low, the SUPC asserts the reset signal of the core `vddcore_nreset` signal until VDDIO is valid. Likewise, if the brownout detector detects a core voltage level VDDCORE that is too low, the SUPC asserts the reset signal `vddcore_nreset` until VDDCORE is valid.

When Backup mode is entered, the SUPC sequentially asserts the reset signal of the core power supply `vddcore_nreset` and disables the voltage regulator, in order to supply only the VDDIO power supply. Current consumption is reduced to a few microamps for the backup part retention. Exit from this mode is possible on multiple wakeup sources including an event on WKUP pins, or a clock alarm. To exit this mode, the SUPC operates in the same way as system startup.

### 23.4.2 Slow Clock Generator

The SUPC embeds a slow clock generator that is supplied with the VDDIO power supply. As soon as the VDDIO is supplied, both the 32.768 kHz crystal oscillator and the slow RC oscillator are powered up, but only the slow RC oscillator is enabled. When the slow RC oscillator is selected as the slow clock source, the slow clock stabilizes more quickly than when the 32.768 kHz crystal oscillator is selected.

The user can select the 32.768 kHz crystal oscillator to be the source of the slow clock, as it provides a more accurate frequency than the slow RC oscillator. The 32.768 kHz crystal oscillator is selected by setting the XTALSEL bit in the SUPC Control register (SUPC\_CR). The following sequence must be used to switch from the slow RC oscillator to the 32.768 kHz crystal oscillator:

1. The PIO lines multiplexed with XIN32 and XOUT32 are configured to be driven by the oscillator.
2. The 32.768 kHz crystal oscillator is enabled.
3. A number of slow RC oscillator clock periods is counted to cover the startup time of the 32.768 kHz crystal oscillator. Refer to the section “Electrical Characteristics” for information on the 32.768 kHz crystal oscillator startup time.
4. The slow clock is switched to the output of the 32.768 kHz crystal oscillator.
5. The slow RC oscillator is disabled to save power.

The switching time may vary depending on the slow RC oscillator clock frequency range. The switch of the slow clock source is glitch-free. The OSCSEL bit of the SUPC Status register (SUPC\_SR) indicates when the switch sequence is finished.

Reverting to the slow RC oscillator as a slow clock source is only possible by shutting down the VDDIO power supply.

If the user does not need the 32.768 kHz crystal oscillator, the XIN32 and XOUT32 pins should be left unconnected.

The user can also set the 32.768 kHz crystal oscillator in Bypass mode instead of connecting a crystal. In this case, the user has to provide the external clock signal on XIN32. The input characteristics of the XIN32 pin are given in the section “Electrical Characteristics”. To enter Bypass mode, the OSCBYPASS bit in the Mode register (SUPC\_MR) must be set before setting XTALSEL.

[58. Electrical Characteristics for SAM E70/S70](#)

### 23.4.3 Core Voltage Regulator Control/Backup Low-power Mode

The SUPC controls the embedded voltage regulator.

The voltage regulator automatically adapts its quiescent current depending on the required load current. Refer to the section “Electrical Characteristics”.

The user can switch off the voltage regulator, and thus put the device in Backup mode, by writing a ‘1’ to SUPC\_CR.VROFF.

This asserts the vddcore\_nreset signal after the write resynchronization time, which lasts two slow clock cycles (worst case). Once the vddcore\_nreset signal is asserted, the processor and the peripherals are stopped one slow clock cycle before the core power supply shuts off.

When the internal voltage regulator is not used and VDDCORE is supplied by an external supply, the voltage regulator can be disabled by writing a ‘0’ to SUPC\_MR.ONREG.

**Related Links**

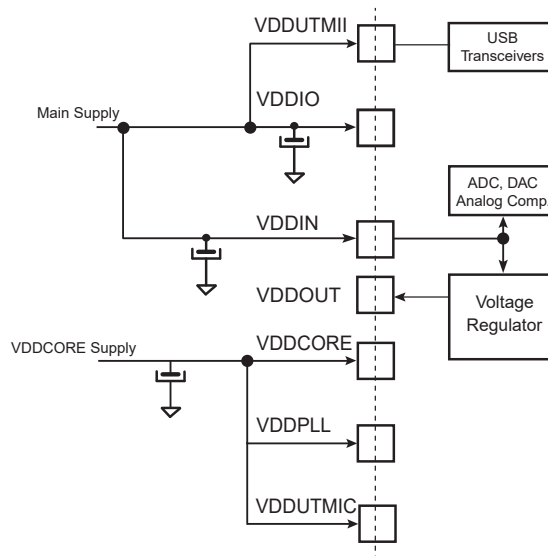

[57. Electrical Characteristics for SAM V70/V71](#)

[58. Electrical Characteristics for SAM E70/S70](#)

### 23.4.4 Using Backup Batteries/Backup Supply

When backup batteries or, more generally, a separate backup supply is used, only VDDIO is present in Backup mode. No other external supply is applied.

**Figure 23-2. Separate Backup Supply Powering Scheme**

**Note: Restrictions**

With main supply < 3.0V, USB is not usable.

With main supply < 2.7V, MediaLB is not usable.

With main supply < 2.0V, ADC, DAC and Analog comparator are not usable.

With main supply and VDDIN > 3V, all peripherals are usable.

# SAM E70/S70/V70/V71

## Supply Controller (SUPC)

When no separate backup supply for VDDIO is used, since the external voltage applied on VDDIO is kept, all of the I/O configurations (i.e., WKUP pin configuration) are maintained in Backup mode. When not using backup batteries, VDDIORDY is set so the user does not need to program it.

**Figure 23-3. No Separate Backup Supply Powering Scheme**

**Note:** Restrictions

with main supply < 2.0 V, USB and ADC/DAC and analog comparator are not usable.

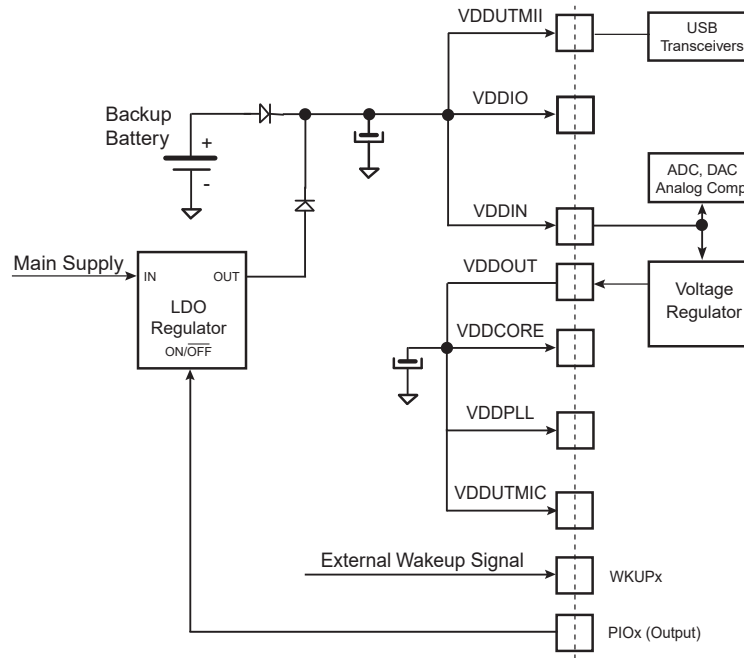

With main supply > 2.0V and < 3V, USB is not usable.

With main supply < 2.7V, MediaLB is not usable.

With main supply > 3V, all peripherals are usable.

The following figure illustrates an example of the powering scheme when using a backup battery. Since the PIO state is preserved when in Backup mode, any free PIO line can be used to switch off the external regulator by driving the PIO line at low level (PIO is input, pull-up enabled after backup reset). System wakeup can be performed using a wakeup pin (WKUPx). See the "[Wakeup Sources](#)" section for further details.

**Figure 23-4. Battery Backup**

Note: The two diodes provide a "switchover circuit" between the backup battery and the main supply when the system is put in Backup mode.

### 23.4.5 Supply Monitor

The SUPC embeds a supply monitor located in the VDDIO power supply and which monitors VDDIO power supply.

The supply monitor can be used to prevent the processor from falling into an unpredictable state if the main power supply drops below a certain level.

**Note:** The supply monitor is disabled by default.

The threshold of the supply monitor is programmable in the SMTH field of the Supply Monitor Mode register (SUPC\_SMMR). Refer to the section "Electrical Characteristics".

The supply monitor can also be enabled during one slow clock period on every one of either 32, 256 or 2048 slow clock periods, depending on the user selection. This is configured in the SUPC\_SMMR.SMSMPL.

Enabling the supply monitor for such reduced times divides the typical supply monitor power consumption by factors of 2, 16 and 128, respectively, if continuous monitoring of the VDDIO power supply is not required.

A supply monitor detection generates either a reset of the core power supply or a wakeup of the core power supply. Generating a core reset when a supply monitor detection occurs is enabled by setting SUPC\_SMMR.SMRSTEN.

Waking up the core power supply when a supply monitor detection occurs can be enabled by setting the SMEN bit in the Wakeup Mode register (SUPC\_WUMR).

The SUPC provides two status bits in the SUPC\_SR for the supply monitor that determine whether the last wakeup was due to the supply monitor:

- SUPC\_SR.SMOS provides real-time information, updated at each measurement cycle or updated at each slow clock cycle, if the measurement is continuous.
- SUPC\_SR.SMS provides saved information and shows a supply monitor detection has occurred since the last read of SUPC\_SR.

The SMS flag generates an interrupt if SUPC\_SMMR.SMIEN is set.

**Figure 23-5. Supply Monitor Status Bit and Associated Interrupt**

### 23.4.6 Backup Power Supply Reset

#### 23.4.6.1 Raising the Backup Power Supply

When the backup voltage VDDIO rises, the slow RC oscillator is powered up and the zero-power power-on reset cell maintains its output low as long as VDDIO has not reached its target voltage. During this period, the SUPC is reset. When the VDDIO voltage becomes valid and the zero-power power-on reset signal is released, a counter is started for five slow clock cycles. This is the time required for the slow RC oscillator to stabilize.

After this time, the voltage regulator is enabled. The core power supply rises and the brownout detector provides the bodcore\_in signal as soon as the core voltage VDDCORE is valid. This results in releasing the vddcore\_nreset signal to the Reset Controller after the bodcore\_in signal has been confirmed as being valid for at least one slow clock cycle.

**Figure 23-6. Raising the VDDIO Power Supply**

Note: After "proc\_nreset" rising, the core starts fetching instructions from Flash.

### 23.4.7 Core Reset

The Supply Controller manages the vddcore\_nreset signal to the Reset Controller, as described in the ["Backup Power Supply Reset"](#) section. The vddcore\_nreset signal is normally asserted before shutting down the core power supply and released as soon as the core power supply is correctly regulated.

There are two additional sources which can be programmed to activate vddcore\_nreset:

- a supply monitor detection
- a brownout detection

#### 23.4.7.1 Supply Monitor Reset

The supply monitor is capable of generating a reset of the system. This is enabled by setting SUPC\_SMMR.SMRSTEN.

If SUPC\_SMMR.SMRSTEN is set and if a supply monitor detection occurs, the vddcore\_nreset signal is immediately activated for a minimum of one slow clock cycle.

#### 23.4.7.2 Brownout Detector Reset

The brownout detector provides the bodcore\_in signal to the SUPC. This signal indicates that the voltage regulation is operating as programmed. If this signal is lost for longer than 1 slow clock period while the voltage regulator is enabled, the SUPC asserts vddcore\_nreset if SUPC\_MR.BODRSTEN is written to '1'.

If SUPC\_MR.BODRSTEN is set and the voltage regulation is lost (output voltage of the regulator too low), the vddcore\_nreset signal is asserted for a minimum of one slow clock cycle and then released if bodcore\_in has been reactivated. SUPC\_SR.BODRSTS indicates the source of the last reset.

Until bodcore\_in is deactivated, the vddcore\_nreset signal remains active.

### 23.4.8 Controlling the SRAM Power Supply

The SUPC can be used to switch on or off the power supply of the backup SRAM by opening or closing the SRAM power switch. This power switch is controlled by SUPC\_MR.BKUPRETEN. However, the battery backup SRAM is automatically switched on when the core power supply is enabled, as the processor requires the SRAM as data memory space.

- If SUPC\_MR.BKUPRETEN is written to '1', there is no immediate effect, but the SRAM will be left powered when the SUPC enters Backup mode, thus retaining its content.
- If SUPC\_MR.BKUPRETEN is written to '0', there is no immediate effect, but the SRAM will be switched off when the SUPC enters Backup mode. The SRAM is automatically switched on when Backup mode is exited.

### 23.4.9 Wakeup Sources

The wakeup events allow the device to exit Backup mode. When a wakeup event is detected, the SUPC performs a sequence that automatically reenables the core power supply.

**Figure 23-7. Wakeup Sources**

#### 23.4.9.1 Wakeup Inputs

The wakeup inputs, WKUPx, can be programmed to perform a wakeup of the core power supply. Each input can be enabled by writing a '1' to the corresponding bit, WKUPENx, in the Wakeup Inputs register (SUPC\_WUIR). The wakeup level can be selected with the corresponding polarity bit, WKUPTx, also located in SUPC\_WUIR.

The resulting signals are wired-ORed to trigger a debounce counter, which is programmed with SUPC\_WUMR.WKUPDBC. This field selects a debouncing period of 3, 32, 512, 4,096 or 32,768 slow clock cycles. The duration of these periods corresponds, respectively, to about 100  $\mu$ s, about 1 ms, about 16 ms, about 128 ms and about 1 second (for a typical slow clock frequency of 32 kHz). Programming SUPC\_WUMR.WKUPDBC to 0 selects an immediate wakeup, i.e., an enabled WKUP pin must be active according to its polarity during a minimum of one slow clock period to wake up the core power supply.

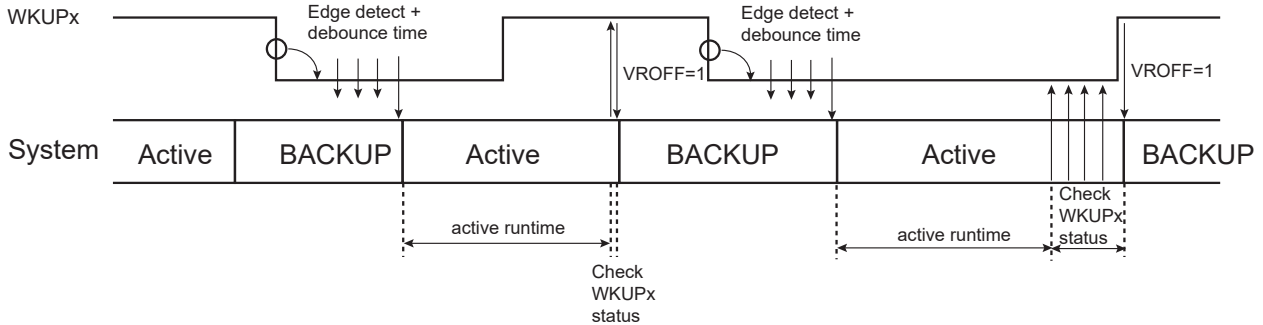

If an enabled WKUP pin is asserted for a duration longer than the debouncing period, a wakeup of the core power supply is started and the signals, WKUP0 to WKUPx as shown in “Wakeup Sources”, are latched in SUPC\_SR. This allows the user to identify the source of the wakeup. However, if a new wakeup condition occurs, the primary information is lost. No new wakeup can be detected since the primary wakeup condition has disappeared.

Before instructing the system to enter Backup mode, if the field SUPC\_WUMR.WKUPDBC > 0, it must be checked that none of the WKUPx pins that are enabled for a wakeup (exit from Backup mode) holds an active polarity. This is checked by reading the pin status in the PIO Controller. If SUPC\_WUIR.WKUPENx=1 and the pin WKUPx holds an active polarity, the system must not be instructed to enter Backup mode.

**Figure 23-8. Entering and Exiting Backup Mode with a WKUP Pin**

WKUPDBC > 0

WKUPTx=0

### 23.4.9.2 Low-power Tamper Detection and Anti-Tampering

Low-power debouncer inputs (WKUP0, WKUP1) can be used for tamper detection. If the tamper sensor is biased through a resistor and constantly driven by the power supply, this leads to power consumption as long as the tamper detection switch is in its active state. To prevent power consumption when the switch is in active state, the tamper sensor circuitry must be intermittently powered, and thus a specific waveform must be applied to the sensor circuitry.

The waveform is generated using RTCOUTx in all modes including Backup mode. Refer to the section “Real-Time Clock (RTC)” for waveform generation.

Separate debouncers are embedded, one for WKUP0 input, one for WKUP1 input.

The WKUP0 and/or WKUP1 inputs perform a system wakeup upon tamper detection. This is enabled by setting SUPC\_WUMR.LPDBCEN0/1.

WKUP0 and/or WKUP1 inputs can also be used when VDDCORE is powered to detect a tamper.

When SUPC\_WUMR.LPDBCENx is written to '1', WKUPx pins must not be configured to act as a debouncing source for the WKUPDBC counter (WKUPENx must be cleared in SUPC\_WUIR).

Low-power tamper detection or debounce requires RTC output (RTCOUTx) to be configured to generate a duty cycle programmable pulse (i.e., OUT0 = 0x7 in RTC\_MR) in order to create the sampling points of both debouncers. The sampling point is the falling edge of the RTCOUTx waveform.

The following figure shows an example of an application where two tamper switches are used. RTCOUTx powers the external pull-up used by the tamper sensor circuitry.

**Figure 23-9. Low-power Debouncer (Push-to-Make Switch, Pull-up Resistors)**

**Figure 23-10. Low-power Debouncer (Push-to-Break Switch, Pull-down Resistors)**

The debouncing period duration is configurable. The period is set for all debouncers (i.e., the duration cannot be adjusted for each debouncer). The number of successive identical samples to wake up the system can be configured from 2 up to 8 in SUPC\_WUMR.LPDBC. The period of time between two samples can be configured by programming RTC\_MR.TPERIOD. Power parameters can be adjusted by modifying the period of time in RTC\_MR.THIGH.

The wakeup polarity of the inputs can be independently configured by writing SUPC\_WUMR.WKUPT0 and/or SUPC\_WUMR.WKUPT1.

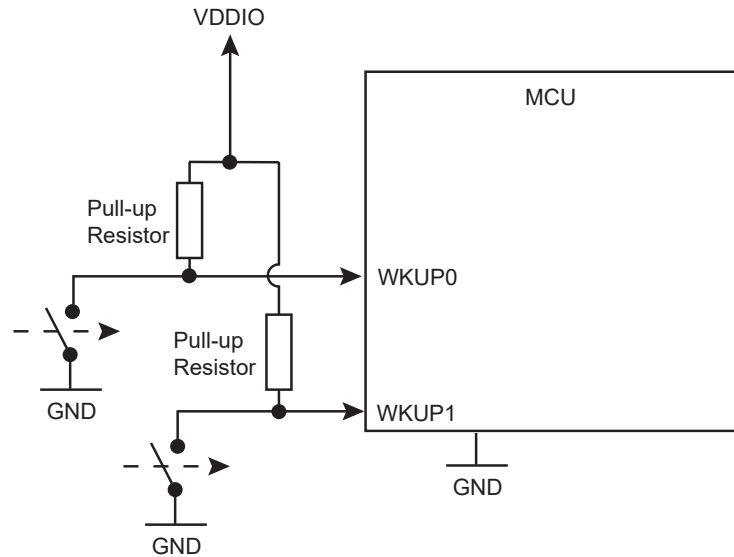

In order to determine which wakeup/tamper pin triggers the system wakeup, a status flag is associated for each low-power debouncer. These flags are read in SUPC\_SR.

A debounce event (tamper detection) can perform an immediate clear (0 delay) on the first half the general-purpose backup registers (GPBR). SUPC\_WUMR.LPDBCCLR bit must be set.

Note that it is not mandatory to use the RTCOUTx pin when using the WKUP0/WKUP1 pins as tampering inputs in any mode. Using the RTCOUTx pin provides a “sampling mode” to further reduce the power consumption of the tamper detection circuitry. If RTCOUTx is not used, the RTC must be configured to create an internal sampling point for the debouncer logic. The period of time between two samples can be configured by programming RTC\_MR.TPERIOD.

The following figure illustrates the use of WKUPx without the RTCOUTx pin.

**Figure 23-11. Using WKUP Pins Without RTCOUTx Pins**

#### 23.4.9.3 Clock Alarms

The RTC and the RTT alarms can generate a wakeup of the core power supply. This can be enabled by setting, respectively, SUPC\_WUMR.RTCEN and SUPC\_WUMR.RTTEN.

The Supply Controller does not provide any status as the information is available in the user interface of either the Real-Time Timer or the Real-Time Clock.

#### 23.4.9.4 Supply Monitor Detection

The supply monitor can generate a wakeup of the core power supply. See "[Supply Monitor](#)".

#### 23.4.10 Register Write Protection

To prevent any single software error from corrupting SYSC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the "[System Controller Write Protection Mode Register](#)" (SYSC\_WPMR).

The following registers can be write-protected:

- [RSTC Mode Register](#)<sup>(1)</sup>
- [RTT Mode Register](#)<sup>(2)</sup>
- [RTT Alarm Register](#)<sup>(2)</sup>
- [RTC Control Register](#)<sup>(3)</sup>
- [RTC Mode Register](#)<sup>(3)</sup>
- [RTC Time Alarm Register](#)<sup>(3)</sup>

### 23.5.1 Supply Controller Control Register

**Name:** SUPC\_CR  
**Offset:** 0x00  
**Property:** Write-only

#### Bits 31:24 – KEY[7:0] Password

| Value | Name   | Description   |
|-------|--------|---|
| 0xA5  | PASSWD | Writing any other value in this field aborts the write operation. |

#### Bit 3 – XTALSEL Crystal Oscillator Select

Note: This bit is located in the VDDIO domain.

| Value | Description  |
|-------|--|
| 0     | (NO_EFFECT): No effect.  |
| 1     | (CRYSTAL_SEL): If KEY is correct, XTALSEL switches the slow clock on the 32.768 kHz crystal oscillator output. |

#### Bit 2 – VROFF Voltage Regulator Off

Note: This bit is located in the VDDIO domain.

| Value | Description   |
|-------|---|
| 0     | (NO_EFFECT): No effect.   |
| 1     | (STOP_VREG): If KEY is correct, VROFF asserts the vddcore_nreset and stops the voltage regulator. |

### 23.5.2 Supply Controller Supply Monitor Mode Register

**Name:** SUPC\_SMMR  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

This register is located in the VDDIO domain.

|        |    |    |       |         |           |     |             |     |
|--------|----|----|-------|---------|-----------|-----|-------------|-----|
| Bit    | 31 | 30 | 29    | 28      | 27        | 26  | 25          | 24  |
| Access |    |    |       |         |           |     |             |     |
| Reset  |    |    |       |         |           |     |             |     |
| Bit    | 23 | 22 | 21    | 20      | 19        | 18  | 17          | 16  |
| Access |    |    |       |         |           |     |             |     |
| Reset  |    |    |       |         |           |     |             |     |
| Bit    | 15 | 14 | 13    | 12      | 11        | 10  | 9           | 8   |
| Access |    |    | SMIEN | SMRSTEN |           |     | SMSMPL[2:0] |     |
| Reset  |    |    | R/W   | R/W     |           |     | R/W         | R/W |
| Reset  |    |    | 0     | 0       |           |     | 0           | 0   |
| Bit    | 7  | 6  | 5     | 4       | 3         | 2   | 1           | 0   |
| Access |    |    |       |         | SMTH[3:0] |     |             |     |
| Reset  |    |    |       |         | R/W       | R/W | R/W         | R/W |
| Reset  |    |    |       |         | 0         | 0   | 0           | 0   |

#### Bit 13 – SMIEN Supply Monitor Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | (NOT_ENABLE): The SUPC interrupt signal is not affected when a supply monitor detection occurs. |
| 1     | (ENABLE): The SUPC interrupt signal is asserted when a supply monitor detection occurs.         |

#### Bit 12 – SMRSTEN Supply Monitor Reset Enable

| Value | Description  |
|-------|--|
| 0     | (NOT_ENABLE): The core reset signal vddcore_nreset is not affected when a supply monitor detection occurs. |
| 1     | (ENABLE): The core reset signal, vddcore_nreset is asserted when a supply monitor detection occurs.        |

#### Bits 10:8 – SMSMPL[2:0] Supply Monitor Sampling Period

| Value | Name     | Description   |
|-------|----------|---|
| 0x0   | SMD      | Supply Monitor disabled   |
| 0x1   | CSM      | Continuous Supply Monitor                                       |
| 0x2   | 32SLCK   | Supply Monitor enabled one SLCK period every 32 SLCK periods    |
| 0x3   | 256SLCK  | Supply Monitor enabled one SLCK period every 256 SLCK periods   |
| 0x4   | 2048SLCK | Supply Monitor enabled one SLCK period every 2,048 SLCK periods |

#### Bits 3:0 – SMTH[3:0] Supply Monitor Threshold

Selects the threshold voltage of the supply monitor. Refer to the section “Electrical Characteristics” for voltage values.

#### Bits 31:24 – KEY[7:0] Password Key

| Value | Name   | Description   |
|-------|--------|---|
| 0xA5  | PASSWD | Writing any other value in this field aborts the write operation. |

#### Bit 20 – OSCBYPASS Oscillator Bypass

**Note:** This bit is located in the VDDIO domain.

| Value | Description  |
|-------|--|
| 0     | (NO_EFFECT): No effect. Clock selection depends on the value of SUPC_CR.XTALSEL.   |
| 1     | (BYPASS): The 32.768 kHz crystal oscillator is bypassed if SUPC_CR.XTALSEL is set. OSCBYPASS must be set prior to setting XTALSEL. |

#### Bit 17 – BKUPRETON SRAM On In Backup Mode

| Value  | Description                                |
|--|--|
| 0  | SRAM (Backup) switched off in Backup mode. |
| 1  | SRAM (Backup) switched on in Backup mode.  |
| Note: This bit is located in the VDDIO domain. |  |

#### Bit 14 – ONREG Voltage Regulator Enable

**Note:** This bit is located in the VDDIO domain.

| Value | Description   |
|-------|---|
| 0     | (ONREG_UNUSED): Internal voltage regulator is not used (external power supply is used). |
| 1     | (ONREG_USED): Internal voltage regulator is used.                                       |

#### Bit 13 – BODDIS Brownout Detector Disable

**Note:** This bit is located in the VDDIO domain.

| Value | Description                                      |
|-------|--|
| 0     | (ENABLE): The core brownout detector is enabled. |

# SAM E70/S70/V70/V71

## Supply Controller (SUPC)

---

---

| Value | Description  |
|-------|--|
| 1     | (DISABLE): The core brownout detector is disabled. |

**Bit 12 – BODRSTEN** Brownout Detector Reset Enable

**Note:** This bit is located in the VDDIO domain.

| Value | Description  |
|-------|--|
| 0     | (NOT_ENABLE): The core reset signal vddcore_nreset is not affected when a brownout detection occurs. |
| 1     | (ENABLE): The core reset signal, vddcore_nreset is asserted when a brownout detection occurs.        |

### 23.5.4 Supply Controller Wakeup Mode Register

**Name:** SUPC\_WUMR  
**Offset:** 0x0C  
**Reset:** 0x00000000  
**Property:** Read/Write

This register is located in the VDDIO domain.

|        |     |          |          |          |     |       |       |              |     |     |
|--------|-----|----------|----------|----------|-----|-------|-------|--------------|-----|-----|

| Access |     | R/W      | R/W      | R/W      |     | R/W   | R/W   | R/W          |     |     |
| Reset  |     | 0        | 0        | 0        |     | 0     | 0     | 0            |     |     |

#### Bits 18:16 – LPDBC[2:0] Low-power Debouncer Period

| Value | Name     | Description  |
|-------|----------|--|
| 0     | DISABLE  | Disables the low-power debouncers.                           |
| 1     | 2_RTCOUT | WKUP0/1 in active state for at least 2 RTCOUTx clock periods |
| 2     | 3_RTCOUT | WKUP0/1 in active state for at least 3 RTCOUTx clock periods |
| 3     | 4_RTCOUT | WKUP0/1 in active state for at least 4 RTCOUTx clock periods |
| 4     | 5_RTCOUT | WKUP0/1 in active state for at least 5 RTCOUTx clock periods |
| 5     | 6_RTCOUT | WKUP0/1 in active state for at least 6 RTCOUTx clock periods |
| 6     | 7_RTCOUT | WKUP0/1 in active state for at least 7 RTCOUTx clock periods |
| 7     | 8_RTCOUT | WKUP0/1 in active state for at least 8 RTCOUTx clock periods |

#### Bits 14:12 – WKUPDBC[2:0] Wakeup Inputs Debouncer Period

| Value | Name       | Description  |
|-------|------------|--|
| 0     | IMMEDIATE  | Immediate, no debouncing, detected active at least on one Slow Clock edge. |
| 1     | 3_SLCK     | WKUPx shall be in its active state for at least 3 SLCK periods             |
| 2     | 32_SLCK    | WKUPx shall be in its active state for at least 32 SLCK periods            |
| 3     | 512_SLCK   | WKUPx shall be in its active state for at least 512 SLCK periods           |
| 4     | 4096_SLCK  | WKUPx shall be in its active state for at least 4,096 SLCK periods         |
| 5     | 32768_SLCK | WKUPx shall be in its active state for at least 32,768 SLCK periods        |

#### Bit 7 – LPDBCCLR Low-power Debouncer Clear

| Value | Description  |
|-------|--|
| 0     | (NOT_ENABLE): A low-power debounce event does not create an immediate clear on the first half of GPBR registers.         |
| 1     | (ENABLE): A low-power debounce event on WKUP0 or WKUP1 generates an immediate clear on the first half of GPBR registers. |

# SAM E70/S70/V70/V71

## Supply Controller (SUPC)

### Bit 6 – LPDBCEN1 Low-power Debouncer Enable WKUP1

| Value | Description   |
|-------|---|
| 0     | (NOT_ENABLE): The WKUP1 input pin is not connected to the low-power debouncer.                    |
| 1     | (ENABLE): The WKUP1 input pin is connected to the low-power debouncer and forces a system wakeup. |

### Bit 5 – LPDBCEN0 Low-power Debouncer Enable WKUP0

| Value | Description   |
|-------|---|
| 0     | (NOT_ENABLE): The WKUP0 input pin is not connected to the low-power debouncer.                    |
| 1     | (ENABLE): The WKUP0 input pin is connected to the low-power debouncer and forces a system wakeup. |

### Bit 3 – RTCEN Real-time Clock Wakeup Enable

| Value | Description  |
|-------|--|
| 0     | (NOT_ENABLE): The RTC alarm signal has no wakeup effect.                   |
| 1     | (ENABLE): The RTC alarm signal forces the wakeup of the core power supply. |

### Bit 2 – RTTEN Real-time Timer Wakeup Enable

| Value | Description  |
|-------|--|
| 0     | (NOT_ENABLE): The RTT alarm signal has no wakeup effect.                   |
| 1     | (ENABLE): The RTT alarm signal forces the wakeup of the core power supply. |

### Bit 1 – SMEN Supply Monitor Wakeup Enable

| Value | Description  |
|-------|--|
| 0     | (NOT_ENABLE): The supply monitor detection has no wakeup effect.                   |
| 1     | (ENABLE): The supply monitor detection forces the wakeup of the core power supply. |

### 23.5.5 Supply Controller Wakeup Inputs Register

**Name:** SUPC\_WUIR  
**Offset:** 0x10  
**Reset:** 0x00000000  
**Property:** Read/Write

This register is located in the VDDIO domain. This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC\_WPMR).

|        |              |     |     |     |     |     |     |     |

| Reset  | 0            | 0   | 0   | 0   | 0   | 0   | 0   | –   |

#### Bits 29:16 – WKUPT[13:0] Wakeup Input Type ('x' = 0-13)

| Value | Description  |
|-------|--|
| 0     | (LOW): A falling edge followed by a low level for a period defined by WKUPDBC on the corresponding wakeup input forces the wakeup of the core power supply.  |
| 1     | (HIGH): A rising edge followed by a high level for a period defined by WKUPDBC on the corresponding wakeup input forces the wakeup of the core power supply. |

#### Bits 13:0 – WKUPEN[13:0] Wakeup Input Enablex ('x' = 0-13)

| Value | Description  |
|-------|--|
| 0     | (DISABLE): The corresponding wakeup input has no wakeup effect.                            |
| 1     | (ENABLE): The corresponding wakeup input is enabled for a wakeup of the core power supply. |

### 23.5.6 Supply Controller Status Register

**Name:** SUPC\_SR  
**Offset:** 0x14  
**Reset:** 0x00000000  
**Property:** Read-only

**Note:** Because of the asynchronism between the Slow Clock (SLCK) and the System Clock (MCK), the status register flag reset is taken into account only 2 slow clock cycles after the read of the SUPC\_SR.

This register is located in the VDDIO domain.

|        |              |      |         |        |         |      |       |    |
|--------|--------------|------|---------|--------|---------|------|-------|----|
| Bit    | 31           | 30   | 29      | 28     | 27      | 26   | 25    | 24 |

**Bits 29:16 – WKUPIS[13:0]** WKUPx ('x' = 0-13) Input Status (cleared on read)

| Value | Description  |
|-------|--|
| 0     | (DIS): The corresponding wakeup input is disabled, or was inactive at the time the debouncer triggered a wakeup event.             |
| 1     | (EN): The corresponding wakeup input was active at the time the debouncer triggered a wakeup event since the last read of SUPC_SR. |

**Bit 14 – LPDBCS1** Low-power Debouncer Wakeup Status on WKUP1 (cleared on read)

| Value | Description   |
|-------|---|
| 0     | (NO): No wakeup due to the assertion of the WKUP1 pin has occurred since the last read of SUPC_SR.                |
| 1     | (PRESENT): At least one wakeup due to the assertion of the WKUP1 pin has occurred since the last read of SUPC_SR. |

**Bit 13 – LPDBCS0** Low-power Debouncer Wakeup Status on WKUP0 (cleared on read)

| Value | Description   |
|-------|---|
| 0     | (NO): No wakeup due to the assertion of the WKUP0 pin has occurred since the last read of SUPC_SR.                |
| 1     | (PRESENT): At least one wakeup due to the assertion of the WKUP0 pin has occurred since the last read of SUPC_SR. |

**Bit 7 – OSCSEL** 32-kHz Oscillator Selection Status

| Value | Description   |
|-------|---|
| 0     | (RC): The slow clock, SLCK, is generated by the slow RC oscillator.               |
| 1     | (CRYST): The slow clock, SLCK, is generated by the 32.768 kHz crystal oscillator. |

**Bit 6 – SMOS** Supply Monitor Output Status

| Value | Description  |
|-------|--|
| 0     | (HIGH): The supply monitor detected VDDIO higher than its threshold at its last measurement. |
| 1     | (LOW): The supply monitor detected VDDIO lower than its threshold at its last measurement.   |

**Bit 5 – SMS** Supply Monitor Status (cleared on read)

| Value | Description  |
|-------|--|
| 0     | (NO): No supply monitor detection since the last read of SUPC_SR.                |
| 1     | (PRESENT): At least one supply monitor detection since the last read of SUPC_SR. |

**Bit 4 – SMRSTS** Supply Monitor Reset Status (cleared on read)

| Value | Description   |
|-------|---|
| 0     | (NO): No supply monitor detection has generated a core reset since the last read of the SUPC_SR.                |
| 1     | (PRESENT): At least one supply monitor detection has generated a core reset since the last read of the SUPC_SR. |

**Bit 3 – BODRSTS** Brownout Detector Reset Status (cleared on read)

When the voltage remains below the defined threshold, there is no rising edge event at the output of the brownout detection cell. The rising edge event occurs only when there is a voltage transition below the threshold.

| Value | Description   |
|-------|---|
| 0     | (NO): No core brownout rising edge event has been detected since the last read of the SUPC_SR.                  |
| 1     | (PRESENT): At least one brownout output rising edge event has been detected since the last read of the SUPC_SR. |

**Bit 2 – SMWS** Supply Monitor Detection Wakeup Status (cleared on read)

| Value | Description   |
|-------|---|
| 0     | (NO): No wakeup due to a supply monitor detection has occurred since the last read of SUPC_SR.                |
| 1     | (PRESENT): At least one wakeup due to a supply monitor detection has occurred since the last read of SUPC_SR. |

**Bit 1 – WKUPS** WKUP Wakeup Status (cleared on read)

| Value | Description   |
|-------|---|
| 0     | (NO): No wakeup due to the assertion of the WKUP pins has occurred since the last read of SUPC_SR.                |
| 1     | (PRESENT): At least one wakeup due to the assertion of the WKUP pins has occurred since the last read of SUPC_SR. |

| Value    | Name   | Description   |
|----------|--------|---|
| 0x525443 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit.<br>Always reads as 0. |

**Bit 0 – WPEN** Write Protection Enable

See "[Register Write Protection](#)" for the list of registers that can be write-protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x525443 ("RTC" in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x525443 ("RTC" in ASCII).  |

## 24. Watchdog Timer (WDT)

### 24.1 Description

The Watchdog Timer (WDT) is used to prevent system lock-up if the software becomes trapped in a deadlock. It features a 12-bit down counter that allows a watchdog period of up to 16 seconds (slow clock around 32 kHz). It can generate a general reset or a processor reset only. In addition, it can be stopped while the processor is in Debug mode or Sleep mode (Idle mode).

### 24.2 Embedded Characteristics

- 12-bit Key-protected Programmable Counter
- Watchdog Clock is Independent from Processor Clock
- Provides Reset or Interrupt Signals to the System
- Counter May Be Stopped while the Processor is in Debug State or in Idle Mode

### 24.3 Block Diagram

Figure 24-1. Watchdog Timer Block Diagram

### 24.4 Functional Description

The Watchdog Timer is used to prevent system lock-up if the software becomes trapped in a deadlock. It is supplied with VDDCORE. It restarts with initial values on processor reset.

The watchdog is built around a 12-bit down counter, which is loaded with the value defined in the field WDV of the Mode Register (WDT\_MR). The Watchdog Timer uses the slow clock divided by 128 to establish the maximum watchdog period to be 16 seconds (with a typical slow clock of 32.768 kHz).

After a processor reset, the value of WDV is 0xFFFF, corresponding to the maximum value of the counter with the external reset generation enabled (field WDRSTEN at 1 after a backup reset). This means that a default watchdog is running at reset, i.e., at power-up. The user can either disable the WDT by setting bit WDT\_MR.WDDIS or reprogram the WDT to meet the maximum watchdog period the application requires.

When setting the WDDIS bit, and while it is set, the fields WDV and WDD must not be modified.

If the watchdog is restarted by writing into the Control Register (WDT\_CR), WDT\_MR must not be programmed during a period of time of three slow clock periods following the WDT\_CR write access. In any case, programming a new value in WDT\_MR automatically initiates a restart instruction.

WDT\_MR can be written only once. Only a processor reset resets it. Writing WDT\_MR reloads the timer with the newly programmed mode parameters.

In normal operation, the user reloads the watchdog at regular intervals before the timer underflow occurs, by setting bit WDT\_CR.WDRSTT. The watchdog counter is then immediately reloaded from WDT\_MR and restarted, and the slow clock 128 divider is reset and restarted. WDT\_CR is write-protected. As a result, writing WDT\_CR without the correct hard-coded key has no effect. If an underflow does occur, the “wdt\_fault” signal to the Reset Controller is asserted if bit WDT\_MR.WDRSTEN is set. Moreover, the bit WDUNF is set in the Status Register (WDT\_SR).

The reload of the watchdog must occur while the watchdog counter is within a window between 0 and WDD. WDD is defined in WDT\_MR.

Any attempt to restart the watchdog while the watchdog counter is between WDV and WDD results in a watchdog error, even if the watchdog is disabled. The bit WDT\_SR.WDERR is updated and the “wdt\_fault” signal to the Reset Controller is asserted.

Note that this feature can be disabled by programming a WDD value greater than or equal to the WDV value. In such a configuration, restarting the Watchdog Timer is permitted in the whole range [0; WDV] and does not generate an error. This is the default configuration on reset (the WDD and WDV values are equal).

The status bits WDUNF (Watchdog Underflow) and WDERR (Watchdog Error) trigger an interrupt, provided the bit WDT\_MR.WDFIEN is set. The signal “wdt\_fault” to the Reset Controller causes a watchdog reset if the WDRSTEN bit is set as already explained in the Reset Controller documentation. In this case, the processor and the Watchdog Timer are reset, and the WDERR and WDUNF flags are reset.

If a reset is generated or if WDT\_SR is read, the status bits are reset, the interrupt is cleared, and the “wdt\_fault” signal to the reset controller is deasserted.

Writing WDT\_MR reloads and restarts the down counter.

While the processor is in debug state or in Sleep mode, the counter may be stopped depending on the value programmed for the bits WDIDLEHLT and WDDBGHLT in WDT\_MR.

**Figure 24-2. Watchdog Behavior**

## 24.5 Register Summary

| Offset | Name   | Bit Pos. | 7        | 6 | 5         | 4       | 3         | 2 | 1     | 0      |  |

### 24.5.1 Watchdog Timer Control Register

**Name:** WDT\_CR  
**Offset:** 0x00  
**Reset:** –  
**Property:** Write-only

The WDT\_CR register values must not be modified within three slow clock periods following a restart of the watchdog performed by a write access in WDT\_CR. Any modification will cause the watchdog to trigger an end of period earlier than expected.

|        |          |    |    |    |    |    |    |        |

| Reset  |          |    |    |    |    |    |    | –      |

#### Bits 31:24 – KEY[7:0] Password

| Value | Name   | Description   |
|-------|--------|---|
| 0xA5  | PASSWD | Writing any other value in this field aborts the write operation. |

#### Bit 0 – WDRSTT Watchdog Restart

| Value | Description                                      |
|-------|--|
| 0     | No effect.                                       |
| 1     | Restarts the watchdog if KEY is written to 0xA5. |

### 24.5.2 Watchdog Timer Mode Register

**Name:** WDT\_MR  
**Offset:** 0x04  
**Reset:** 0x3FFF2FFF  
**Property:** Read/Write Once

The first write access prevents any further modification of the value of this register. Read accesses remain possible.

The WDT\_MR register values must not be modified within three slow clock periods following a restart of the watchdog performed by a write access in WDT\_CR. Any modification will cause the watchdog to trigger an end of period earlier than expected.

#### Bit 29 – WDIDLEHLT Watchdog Idle Halt

| Value | Description  |
|-------|--|
| 0     | The watchdog runs when the system is in idle state.  |
| 1     | The watchdog stops when the system is in idle state. |

#### Bit 28 – WDDBGHLT Watchdog Debug Halt

| Value | Description  |
|-------|--|
| 0     | The watchdog runs when the processor is in debug state.  |
| 1     | The watchdog stops when the processor is in debug state. |

#### Bits 27:16 – WDD[11:0] Watchdog Delta Value

Defines the permitted range for reloading the Watchdog Timer.  
 If the Watchdog Timer value is less than or equal to WDD, setting bit WDT\_CR.WDRSTT restarts the timer.  
 If the Watchdog Timer value is greater than WDD, setting bit WDT\_CR.WDRSTT causes a watchdog error.

#### Bit 15 – WDDIS Watchdog Disable

When setting the WDDIS bit, and while it is set, the fields WDV and WDD must not be modified.

| Value | Description                  |
|-------|------------------------------|
| 0     | Enables the Watchdog Timer.  |
| 1     | Disables the Watchdog Timer. |

#### Bit 13 – WDRSTEN Watchdog Reset Enable

| Value | Description  |
|-------|--|
| 0     | A watchdog fault (underflow or error) has no effect on the resets. |

# SAM E70/S70/V70/V71

## Watchdog Timer (WDT)

---

---

| Value | Description  |
|-------|--|
| 1     | A watchdog fault (underflow or error) triggers a watchdog reset. |

**Bit 12 – WDFIEN** Watchdog Fault Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | A watchdog fault (underflow or error) has no effect on interrupt. |
| 1     | A watchdog fault (underflow or error) asserts interrupt.          |

**Bits 11:0 – WDV[11:0]** Watchdog Counter Value  
Defines the value loaded in the 12-bit watchdog counter.

### 24.5.3 Watchdog Timer Status Register

**Name:** WDT\_SR  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read-only

**Bit 1 – WDERR** Watchdog Error (cleared on read)

| Value | Description   |
|-------|---|
| 0     | No watchdog error occurred since the last read of WDT_SR.           |
| 1     | At least one watchdog error occurred since the last read of WDT_SR. |

**Bit 0 – WDUNF** Watchdog Underflow (cleared on read)

| Value | Description   |
|-------|---|
| 0     | No watchdog underflow occurred since the last read of WDT_SR.           |
| 1     | At least one watchdog underflow occurred since the last read of WDT_SR. |

## **25. Reinforced Safety Watchdog Timer (RSWDT)**

### **25.1 Description**

The Reinforced Safety Watchdog Timer (RSWDT) works in parallel with the Watchdog Timer (WDT) to reinforce safe watchdog operations.

The RSWDT can be used to reinforce the safety level provided by the WDT in order to prevent system lock-up if the software becomes trapped in a deadlock. The RSWDT works in a fully operable mode, independent of the WDT. The RSWDT clock source is automatically selected from either the Slow RC oscillator clock, or from the Main RC oscillator divided clock to get an equivalent Slow RC oscillator clock. If the WDT clock source (for example, the 32 kHz crystal oscillator) fails, the system lock-up is no longer monitored by the WDT because the RSWDT performs the monitoring. Thus, there is no lack of safety regardless of the external operating conditions. The RSWDT shares the same features as the WDT (i.e., a 12-bit down counter that allows a watchdog period of up to 16 seconds with slow clock at 32.768 kHz). It can generate a general reset or a processor reset only. In addition, it can be stopped while the processor is in Debug mode or Idle mode.

### **25.2 Embedded Characteristics**

- Automatically Selected Reliable RSWDT Clock Source (independent of WDT clock source)
- 12-bit Key-protected Programmable Counter
- Provides Reset or Interrupt Signals to the System
- Counter may be Stopped While Processor is in Debug State or Idle Mode

## 25.3 Block Diagram

Figure 25-1. Reinforced Safety Watchdog Timer Block Diagram

## 25.4 Functional Description

The RSWDT is supplied by VDDCORE. The RSWDT is initialized with default values on processor reset or on a power-on sequence and is disabled (its default mode) under such conditions.

The RSWDT must not be enabled if the WDT is disabled.

The Main RC oscillator divided clock is selected if the Main RC oscillator is already enabled by the application (CKGR\_MOR.MOSCRGEN = 1) or if the WDT is driven by the Slow RC oscillator.

The RSWDT is built around a 12-bit down counter, which is loaded with a slow clock value other than that of the slow clock in the WDT, defined in the WDV (Watchdog Counter Value) field of the Mode Register (RSWDT\_MR). The RSWDT uses the slow clock divided by 128 to establish the maximum watchdog period to be 16 seconds (with a typical slow clock of 32.768 kHz).

After a processor reset, the value of the RSWDT\_MR.WDV is 0xFFFF, corresponding to the maximum value of the counter with the external reset generation enabled (RSWDT\_MR.WDRSTEN = 1 after a backup reset). This means that a default watchdog is running at reset, that is, at power up.

If the watchdog is restarted by writing into the Control Register (RSWDT\_CR), the RSWDT\_MR must not be programmed during a period of time of three slow clock periods following the RSWDT\_CR write access. Programming a new value in the RSWDT\_MR, automatically initiates a restart instruction.

The RSWDT\_MR can be written only once. Only a processor reset resets it. Writing the RSWDT\_MR reloads the timer with the newly programmed mode parameters.

# SAM E70/S70/V70/V71

## Reinforced Safety Watchdog Timer (RSWDT)

In normal operation, the user reloads the watchdog at regular intervals before the timer underflow occurs, by setting the RSWDT\_CR.WDRSTT bit. The watchdog counter is then immediately reloaded from the RSWDT\_MR and restarted, and the slow clock 128 divider is reset and restarted. The RSWDT\_CR is write-protected. As a result, writing the RSWDT\_CR without the correct hard-coded key has no effect. If an underflow does occur, the “wdt\_fault” signal to the Reset Controller is asserted if the RSWDT\_MR.WDRSTEN is set. Moreover, Watchdog Underflow (WDUNF) is set in the Status Register (RSWDT\_SR).

The status bits WDUNF and WDERR trigger an interrupt, provided the WDFIEN bit is set in the RSWDT\_MR. The signal “wdt\_fault” to the Reset Controller causes a Watchdog reset if the WDRSTEN bit. For additional information, refer to the section “Reset Controller (RSTC)”. In this case, the processor and the RSWDT are reset, and the WDUNF and WDERR flags are reset.

If a reset is generated or if the RSWDT\_SR is read, the status bits are reset, the interrupt is cleared, and the “wdt\_fault” signal to the reset controller is deasserted.

Writing the RSWDT\_MR reloads and restarts the down counter.

The RSWDT is disabled after any power-on sequence.

While the processor is in Debug state or in Idle mode, the counter may be stopped depending on the value programmed for the WDIDLEHLT and WDDBGHLT bits in the RSWDT\_MR.

**CAUTION** The RSWDT must not be enabled if the WDT is disabled.

## Reinforced Safety Watchdog Timer (RSWDT)

### 25.5.3 Reinforced Safety Watchdog Timer Status Register

**Name:** RSWDT\_SR  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 0 – WDUNF Watchdog Underflow

| Value | Description   |
|-------|---|
| 0     | No watchdog underflow occurred since the last read of RSWDT_SR.           |
| 1     | At least one watchdog underflow occurred since the last read of RSWDT_SR. |

## 26. Reset Controller (RSTC)

### 26.1 Description

The Reset Controller (RSTC), driven by Power-On Reset (POR) cells, software, external reset pin and peripheral events, handles all the resets of the system without any external components. It reports which reset occurred last.

The RSTC also drives simultaneously the external reset and the peripheral and processor resets.

### 26.2 Embedded Characteristics

- Driven by embedded POR, software, external reset pin and peripheral events
- Management of all system resets, including:
  - External devices through the NRST pin
  - Processor
  - Peripheral set
- Reset source status:
  - Status of the last reset
  - Either VDDCORE and VDDIO POR, Software Reset, User Reset, Watchdog Reset
- External reset signal control and shaping

### 26.3 Block Diagram

**Figure 26-1. Reset Controller Block Diagram**

## 26.4 Functional Description

### 26.4.1 Overview

The RSTC is made up of an NRST manager and a reset state manager. It runs at SLCK frequency and generates the following reset signals:

- `proc_nreset`: Processor reset line (also resets the Watchdog Timer)
- `periph_nreset`: Affects the whole set of embedded peripherals
- `nrst_out`: Drives the NRST pin

**Note:** `proc_nreset` and `periph_nreset` are driven in the same way.

These reset signals are asserted by the RSTC, either on events generated by peripherals, events on the NRST pin, or on a software action. The reset state manager controls the generation of reset signals and provides a signal to the NRST manager when an assertion of the NRST pin is required.

The NRST manager shapes the NRST assertion during a programmable time, thus controlling external device resets.

The RSTC Mode register (`RSTC_MR`), used to configure the RSTC, is powered with VDDIO, so that its configuration is saved as long as VDDIO is on.

### 26.4.2 NRST Manager

The NRST manager samples the NRST input pin and drives this pin low when required by the reset state manager. The figure below shows the block diagram of the NRST manager.

**Figure 26-2. NRST Manager**

#### 26.4.2.1 NRST Signal or Interrupt

The NRST manager samples the NRST pin at SLCK speed. When the NRST line is low for more than three clock cycles, a User Reset is reported to the reset state manager. The NRST pin must be asserted for at least 1 SLCK clock cycle to ensure execution of a user reset.

However, the NRST manager can be programmed to not trigger a reset when an assertion of NRST occurs. Writing a '0' to `RSTC_MR.URSTEN` disables the User Reset trigger.

The level of the pin NRST can be read at any time in the bit `NRSTL` in the RSTC Status Register (`RSTC_SR`). As soon as the NRST pin is asserted, `RSTC_SR.URSTS` is written to '1'. This bit is cleared only when the `RSTC_SR` is read.

The RSTC can also be programmed to generate an interrupt instead of generating a reset. To do so, `RSTC_MR.URSTIEN` must be set.

#### 26.4.2.2 NRST External Reset Control

The reset state manager asserts the signal `exter_nreset` to assert the NRST pin. When this occurs, the "nrst\_out" signal is driven low by the NRST manager for a time programmed by `RSTC_MR.ERSTL`. This assertion duration, named External Reset Length, lasts  $2^{(ERSTL+1)}$  SLCK cycles. This gives the approximate duration of an assertion between 60  $\mu$ s and 2 seconds. Note that `ERSTL` at '0' defines a two-cycle duration for the NRST pulse.

This feature allows the RSTC to shape the NRST pin level, and thus to guarantee that the NRST line is driven low for a time compliant with potential external devices connected on the system reset.

RSTC\_MR is backed up, making it possible to use the value of ERSTL to shape the system powerup reset for devices requiring a longer startup time than that of the MCU.

### 26.4.3 Reset States

The reset state manager handles the different reset sources and generates the internal reset signals. It reports the reset status in RSTTYP of the Status Register (RSTC\_SR). The update of RSTC\_SR.RSTTYP is performed when the processor reset is released.

#### 26.4.3.1 General Reset

A general reset occurs when a VDDIO POR is detected, a brown out or a voltage regulation loss is detected by the Supply Controller. The vddcore\_nreset signal is asserted by the Supply Controller when a general reset occurs.

All the reset signals are released and RSTC\_SR.RSTTYP reports a general reset. As the RSTC\_MR is written to '0', the NRST line rises two cycles after the vddcore\_nreset, as ERSTL defaults at value 0x0.

The figure below illustrates how the general reset affects the reset signals.

**Figure 26-3. General Reset Timing Diagram**

#### 26.4.3.2 Backup Reset

A backup reset occurs when the chip exits from Backup mode. While exiting Backup mode, the vddcore\_nreset signal is asserted by the Supply Controller.

Field RSTC\_SR.RSTTYP is updated to report a backup reset.

#### 26.4.3.3 Watchdog Reset

The watchdog reset is entered when a watchdog fault occurs. This reset lasts three SLCK cycles.

When in watchdog reset, the processor reset and the peripheral reset are asserted. The NRST line is also asserted, depending on the value of RSTC\_MR.ERSTL. However, the resulting low level on NRST does not result in a user reset state.

The Watchdog Timer is reset by the proc\_nreset signal. As the watchdog fault always causes a processor reset if WDT\_MR.WDRSTEN is written to '1', the Watchdog Timer is always reset after a watchdog reset, and the Watchdog is enabled by default and with a period set to a maximum.

When `WDT_MR.WDRSTEN` is written to '0', the watchdog fault has no impact on the RSTC.

After a watchdog overflow occurs, the report on the `RSTC_SR.RSTTYP` may differ (either `WDT_RST` or `USER_RST`) depending on the external components driving the NRST pin. For example, if the NRST line is driven through a resistor and a capacitor (NRST pin debouncer), the reported value is `USER_RST` if the low to high transition is greater than one `SLCK` cycle.

**Figure 26-4. Watchdog Reset Timing Diagram**

### 26.4.3.4 Software Reset

The RSTC offers commands to assert the different reset signals. These commands are performed by writing the Control register (`RSTC_CR`) with the following bits at '1':

- `RSTC_CR.PROCRST`: Writing a '1' to `PROCRST` resets the processor and all the embedded peripherals, including the memory system and, in particular, the Remap Command.
- `RSTC_CR.EXTRST`: Writing a '1' to `EXTRST` asserts low the NRST pin during a time defined by the field `RSTC_MR.ERSTL`.

The software reset is entered if at least one of these bits is written to '1' by the software. All these commands can be performed independently or simultaneously. The software reset lasts three `SLCK` cycles.

The internal reset signals are asserted as soon as the register write is performed. This is detected on the Host Clock (`MCK`). They are released when the software reset has ended, i.e., synchronously to `SLCK`.

If `EXTRST` is written to '1', the `nrst_out` signal is asserted depending on the configuration of `RSTC_MR.ERSTL`. However, the resulting falling edge on NRST does not lead to a user reset.

If and only if the `RSTC_CR.PROCRST` is written to '1', the RSTC reports the software status in field `RSTC_SR.RSTTYP`. Other software resets are not reported in `RSTTYP`.

As soon as a software operation is detected, `RSTC_SR.SRCMP` is written to '1'. `SRCMP` is cleared at the end of the software reset. No other software reset can be performed while `SRCMP` is written to '1', and writing any value in the `RSTC_CR` has no effect.

**Figure 26-5. Software Reset Timing Diagram**

### 26.4.3.5 User Reset

A user reset is generated when a low level is detected on the NRST pin and RSTC\_MR.URSTEN is at '1'. The NRST input signal is resynchronized with SLCK to ensure proper behavior of the system. Thus, the NRST pin must be asserted for at least 1 SLCK clock cycle to ensure execution of a user reset.

The user reset is triggered 2 SLCK cycles after a low level is detected on NRST. The processor reset and the peripheral reset are asserted.

The user reset ends when NRST rises, after a two-cycle resynchronization time and a three-cycle processor startup. The processor clock is reenabled as soon as NRST is confirmed high.

When the processor reset signal is released, RSTC\_SR.RSTTYP is loaded with the value '4', indicating a user reset.

The NRST manager guarantees that the NRST line is asserted for External Reset Length SLCK cycles, as configured in RSTC\_MR.ERSTL. However, if NRST does not rise after External Reset Length because it is driven low externally, the internal reset lines remain asserted until NRST actually rises.

**Figure 26-6. User Reset Timing Diagram**

#### 26.4.4 Reset State Priorities

The reset state manager manages the priorities among the different reset sources. The resets are listed in order of priority as follows:

1. General reset
2. Backup reset
3. Watchdog reset
4. Software reset
5. User reset

Specific cases are listed below:

- When in user reset:
  - A watchdog event is impossible because the Watchdog Timer is being reset by the `proc_nreset` signal.
  - A software reset is impossible, since the processor reset is being activated.
- When in software reset:
  - A watchdog event has priority over the current state.
  - The NRST has no effect.
- When in watchdog reset:
  - The processor reset is active and so a software reset cannot be programmed.
  - A user reset cannot be entered.

|        |         | 23:16    |          |   |   |         |            |             |       |         |  |
|        |         | 31:24    | KEY[7:0] |   |   |         |            |             |       |         |  |

### 26.4.5.1 RSTC Control Register

**Name:** RSTC\_CR  
**Offset:** 0x00  
**Property:** Write-only

|        |     |          |    |    |    |        |    |    |         |
|--------|-----|----------|----|----|----|--------|----|----|---------|
|        | Bit | 31       | 30 | 29 | 28 | 27     | 26 | 25 | 24      |
|        |     | KEY[7:0] |    |    |    |        |    |    |         |
| Access |     | W        | W  | W  | W  | W      | W  | W  | W       |
| Reset  |     | 0        | 0  | 0  | 0  | 0      | 0  | 0  | –       |
|        |     |          |    |    |    |        |    |    |         |
|        | Bit | 23       | 22 | 21 | 20 | 19     | 18 | 17 | 16      |
| Access |     |          |    |    |    |        |    |    |         |
| Reset  |     |          |    |    |    |        |    |    |         |
|        |     |          |    |    |    |        |    |    |         |
|        | Bit | 15       | 14 | 13 | 12 | 11     | 10 | 9  | 8       |
| Access |     |          |    |    |    |        |    |    |         |
| Reset  |     |          |    |    |    |        |    |    |         |
|        |     |          |    |    |    |        |    |    |         |
|        | Bit | 7        | 6  | 5  | 4  | 3      | 2  | 1  | 0       |
| Access |     |          |    |    |    | EXTRST |    |    | PROCRST |
| Reset  |     |          |    |    |    | –      |    |    | –       |

#### Bits 31:24 – KEY[7:0] System Reset Key

| Value | Name   | Description   |
|-------|--------|---|
| 0xA5  | PASSWD | Writing any other value in this field aborts the write operation. |

#### Bit 3 – EXTRST External Reset

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | If KEY = 0xA5, asserts the NRST pin. |

#### Bit 0 – PROCRST Processor Reset

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | If KEY = 0xA5, resets the processor and all the embedded peripherals. |

### 26.4.5.2 RSTC Status Register

**Name:** RSTC\_SR  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read-only

The register reset value assumes that a general reset has been performed; it is subject to change if other types of reset are generated.

|        |    |    |    |    |    |    |             |       |   |
|--------|----|----|----|----|----|----|-------------|-------|---|
| Bit    | 31 | 30 | 29 | 28 | 27 | 26 | 25          | 24    |   |
|        |    |    |    |    |    |    |             |       |   |
| Access |    |    |    |    |    |    |             |       |   |
| Reset  |    |    |    |    |    |    |             |       |   |
| Bit    | 23 | 22 | 21 | 20 | 19 | 18 | 17          | 16    |   |
|        |    |    |    |    |    |    | SRCMP       | NRSTL |   |
| Access |    |    |    |    |    |    | R           | R     |   |
| Reset  |    |    |    |    |    |    | 0           | 0     |   |
| Bit    | 15 | 14 | 13 | 12 | 11 | 10 | 9           | 8     |   |
|        |    |    |    |    |    |    | RSTTYP[2:0] |       |   |
| Access |    |    |    |    |    |    | R           | R     | R |
| Reset  |    |    |    |    |    |    | 0           | 0     | 0 |
| Bit    | 7  | 6  | 5  | 4  | 3  | 2  | 1           | 0     |   |
|        |    |    |    |    |    |    |             | URSTS |   |
| Access |    |    |    |    |    |    |             | R     |   |
| Reset  |    |    |    |    |    |    |             | 0     |   |

#### Bit 17 – SRCMP Software Reset Command in Progress

When set, this bit indicates that a software reset command is in progress and that no further software reset should be performed until the end of the current one. This bit is automatically cleared at the end of the current software reset.

| Value | Description   |
|-------|---|
| 0     | No software command is being performed by the RSTC. The RSTC is ready for a software command. |
| 1     | A software reset command is being performed by the RSTC. The RSTC is busy.                    |

#### Bit 16 – NRSTL NRST Pin Level

Registers the NRST pin level sampled on each MCK rising edge.

#### Bits 10:8 – RSTTYP[2:0] Reset Type

This field reports the cause of the last processor reset. Reading this RSTC\_SR does not reset this field.

| Value | Name        | Description                              |
|-------|-------------|--|
| 0     | GENERAL_RST | First powerup reset                      |
| 1     | BACKUP_RST  | Return from Backup mode                  |
| 2     | WDT_RST     | Watchdog fault occurred                  |
| 3     | SOFT_RST    | Processor reset required by the software |
| 4     | USER_RST    | NRST pin detected low                    |
| 5     | –           | Reserved                                 |
| 6     | –           | Reserved                                 |
| 7     | –           | Reserved                                 |

#### Bit 0 – URSTS User Reset Status

A high-to-low transition of the NRST pin sets the URSTS. This transition is also detected on the MCK rising edge.

If the user reset is disabled (URSTEN = 0 in RSTC\_MR) and if the interrupt is enabled by RSTC\_MR.URSTIEN, URSTS triggers an interrupt. Reading the RSTC\_SR resets URSTS and clears the interrupt.

# SAM E70/S70/V70/V71

## Reset Controller (RSTC)

---

---

| Value | Description   |
|-------|---|
| 0     | No high-to-low edge on NRST happened since the last read of RSTC_SR.                          |
| 1     | At least one high-to-low transition of NRST has been detected since the last read of RSTC_SR. |

### 26.4.5.3 RSTC Mode Register

**Name:** RSTC\_MR  
**Offset:** 0x08  
**Reset:** 0x00000001  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC\_WPMR).

|        |            |    |    |         |     |     |     |        |
|--------|------------|----|----|---------|-----|-----|-----|--------|
| Bit    | 31         | 30 | 29 | 28      | 27  | 26  | 25  | 24     |
|        | KEY[7:0]   |    |    |         |     |     |     |        |
| Access | W          | W  | W  | W       | W   | W   | W   | W      |
| Reset  | 0          | 0  | 0  | 0       | 0   | 0   | 0   | 0      |
|        |            |    |    |         |     |     |     |        |
| Bit    | 23         | 22 | 21 | 20      | 19  | 18  | 17  | 16     |
| Access |            |    |    |         |     |     |     |        |
| Reset  |            |    |    |         |     |     |     |        |
|        |            |    |    |         |     |     |     |        |
| Bit    | 15         | 14 | 13 | 12      | 11  | 10  | 9   | 8      |
|        | ERSTL[3:0] |    |    |         |     |     |     |        |
| Access |            |    |    |         | R/W | R/W | R/W | R/W    |
| Reset  |            |    |    |         | 0   | 0   | 0   | 0      |
|        |            |    |    |         |     |     |     |        |
| Bit    | 7          | 6  | 5  | 4       | 3   | 2   | 1   | 0      |
|        |            |    |    | URSTIEN |     |     |     | URSTEN |
| Access |            |    |    | R/W     |     |     |     | R/W    |
| Reset  |            |    |    | 0       |     |     |     | 1      |

#### Bits 31:24 – KEY[7:0] Write Access Password

| Value | Name   | Description  |
|-------|--------|--|
| 0xA5  | PASSWD | Writing any other value in this field aborts the write operation. Always reads as 0. |

#### Bits 11:8 – ERSTL[3:0] External Reset Length

This field defines the external reset length. The external reset is asserted during a time of  $2^{(ERSTL+1)}$  SLCK cycles. This allows assertion duration to be programmed between 60  $\mu$ s and 2 seconds. Note that synchronization cycles must also be considered when calculating the actual reset length as previously described.

#### Bit 4 – URSTIEN User Reset Interrupt Enable

| Value | Description   |
|-------|---|
| 0     | RSTC_SR.USRTS at '1' has no effect on the RSTC interrupt line.      |
| 1     | RSTC_SR.USRTS at '1' asserts the RSTC interrupt line if URSTEN = 0. |

#### Bit 0 – URSTEN User Reset Enable

| Value | Description  |
|-------|--|
| 0     | The detection of a low level on the NRST pin does not generate a user reset. |
| 1     | The detection of a low level on the NRST pin triggers a user reset.          |

## 27. Real-time Clock (RTC)

### 27.1 Description

The Real-time Clock (RTC) peripheral is designed for very low power consumption. For optimal functionality, the RTC requires an accurate external 32.768 kHz clock, which can be provided by a crystal oscillator.

It combines a complete time-of-day clock with alarm and a Gregorian or Persian calendar, complemented by a programmable periodic interrupt. The alarm and calendar registers are accessed by a 32-bit data bus.

The time and calendar values are coded in binary-coded decimal (BCD) format. The time format can be 24-hour mode or 12-hour mode with an AM/PM indicator.

Updating time and calendar fields and configuring the alarm fields are performed by a parallel capture on the 32-bit data bus. An entry control is performed to avoid loading registers with incompatible BCD format data or with an incompatible date according to the current month/year/century.

A clock divider calibration circuitry can be used to compensate for crystal oscillator frequency variations.

An RTC output can be programmed to generate several waveforms, including a prescaled clock derived from 32.768 kHz.

### 27.2 Embedded Characteristics

- Full Asynchronous Design for Ultra Low Power Consumption
- Gregorian and Persian Modes Supported
- Programmable Periodic Interrupt
- Safety/security Features:
  - Valid Time and Date Programming Check
  - On-The-Fly Time and Date Validity Check
- Counters Calibration Circuitry to Compensate for Crystal Oscillator Variations
- Waveform Generation
- Register Write Protection

### 27.3 Block Diagram

Figure 27-1. Real-time Clock Block Diagram

## **27.4 Product Dependencies**

### **27.4.1 Power Management**

The Real-time Clock is continuously clocked at 32.768 kHz. The Power Management Controller has no effect on RTC behavior.

### **27.4.2 Interrupt**

Within the System Controller, the RTC interrupt is OR-wired with all the other module interrupts.

Only one System Controller interrupt line is connected on one of the internal sources of the interrupt controller.

RTC interrupt requires the interrupt controller to be programmed first.

When a System Controller interrupt occurs, the service routine must first determine the cause of the interrupt. This is done by reading each status register of the System Controller peripherals successively.

## **27.5 Functional Description**

The RTC provides a full binary-coded decimal (BCD) clock that includes century (19/20), year (with leap years), month, date, day, hours, minutes and seconds reported in [RTC Time Register \(RTC\\_TIMR\)](#).

The valid year range is up to 2099 in Gregorian mode (or 1300 to 1499 in Persian mode).

The RTC can operate in 24-hour mode or in 12-hour mode with an AM/PM indicator.

Corrections for leap years are included (all years divisible by 4 being leap years except 1900). This is correct up to the year 2099.

The RTC can generate configurable waveforms on RTCOUT0/1 outputs.

### **27.5.1 Reference Clock**

The reference clock is the Slow Clock (SLCK) which can be driven internally or by an external 32.768 kHz crystal.

During low-power modes of the processor, the oscillator runs and power consumption is critical. The crystal selection must consider the current consumption for power saving and the frequency drift due to temperature effect on the circuit for time accuracy.

### **27.5.2 Timing**

The RTC is updated in real time at one-second intervals in Normal mode for the counters of seconds, at one-minute intervals for the counter of minutes and so on.

Due to the asynchronous operation of the RTC with respect to the rest of the chip, to be certain that the value read in the RTC registers (century, year, month, date, day, hours, minutes, seconds) are valid and stable, it is necessary to read these registers twice. If the data is the same both times, then it is valid. Therefore, a minimum of two and a maximum of three accesses are required.

### **27.5.3 Alarm**

The RTC has five programmable fields: month, date, hours, minutes and seconds.

Each of these fields can be enabled or disabled to match the alarm condition:

- If all the fields are enabled, an alarm flag is generated (the corresponding flag is asserted and an interrupt generated if enabled) at a given month, date, hour/minute/second.
- If only the "seconds" field is enabled, then an alarm is generated every minute.

Depending on the combination of fields enabled, a large number of possibilities are available to the user ranging from minutes to 365/366 days.

Hour, minute and second matching alarms (SECEN, MINEN, HOUREN) can be enabled independently of SEC, MIN, HOUR fields.

**Note:** To change one of the SEC, MIN, HOUR, DATE, MONTH fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to the RTC\_TIMALR or RTC\_CALALR. The first access clears the enable corresponding to the field to change (SECEN, MINEN, HOUREN, DATEEN, MTHEN). If the field is already cleared, this access is not required. The second access performs the change of the value (SEC, MIN, HOUR, DATE, MONTH). The third access is required to re-enable the field by writing 1 in SECEN, MINEN, HOUREN, DATEEN, MTHEN fields.

### 27.5.4 Error Checking when Programming

Verification on user interface data is performed when accessing the century, year, month, date, day, hours, minutes, seconds and alarms. A check is performed on illegal BCD entries such as illegal date of the month with regard to the year and century configured.

If one of the time fields is not correct, the data is not loaded into the register/counter and a flag is set in the validity register. The user can not reset this flag. It is reset as soon as an acceptable value is programmed. This avoids any further side effects in the hardware. The same procedure is followed for the alarm.

The following checks are performed:

1. Century (check if it is in range 19–20 or 13–14 in Persian mode)
2. Year (BCD entry check)
3. Date (check range 01–31)
4. Month (check if it is in BCD range 01–12, check validity regarding “date”)
5. Day (check range 1–7)
6. Hour (BCD checks: in 24-hour mode, check range 00–23 and check that AM/PM flag is not set if RTC is set in 24-hour mode; in 12-hour mode check range 01–12)
7. Minute (check BCD and range 00–59)
8. Second (check BCD and range 00–59)

**Note:** If the 12-hour mode is selected by means of the RTC Mode Register (RTC\_MR), a 12-hour value can be programmed and the returned value on RTC\_TIMR will be the corresponding 24-hour value. The entry control checks the value of the AM/PM indicator (bit 22 of RTC\_TIMR) to determine the range to be checked.

### 27.5.5 RTC Internal Free Running Counter Error Checking

To improve the reliability and security of the RTC, a permanent check is performed on the internal free running counters to report non-BCD or invalid date/time values.

An error is reported by TDERR bit in the status register (RTC\_SR) if an incorrect value has been detected. The flag can be cleared by setting the TDERRCLR bit in the Status Clear Command Register (RTC\_SCCR).

The TDERR error flag will be set again if the source of the error has not been cleared before clearing the TDERR flag. The clearing of the source of such error can be done by reprogramming a correct value on RTC\_CALR and/or RTC\_TIMR.

The RTC internal free running counters may automatically clear the source of TDERR due to their roll-over (i.e., every 10 seconds for SECONDS[3:0] field in RTC\_TIMR). In this case the TDERR is held high until a clear command is asserted by TDERRCLR bit in RTC\_SCCR.

### 27.5.6 Updating Time/Calendar

#### 27.5.6.1 Description

The update of the time/calendar must be synchronized on a second periodic event by either polling the RTC\_SR.SEC status bit or by enabling the SECEN interrupt in the RTC\_IER register.

Once the second event occurs, the user must stop the RTC by setting the corresponding field in the Control Register (RTC\_CR). Bit UPDTIM must be set to update time fields (hour, minute, second) and bit UPDCAL must be set to update calendar fields (century, year, month, date, day).

The ACKUPD bit must then be read to 1 by either polling the RTC\_SR or by enabling the ACKUPD interrupt in the RTC\_IER. Once ACKUPD is read to 1, it is mandatory to clear this flag by writing the corresponding bit in the RTC\_SCCR, after which the user can write to the Time Register, the Calendar Register, or both. Only the ACKUPD interrupt can be enabled while updating time/calendar, all others RTC interrupts must be disabled.

Once the update is finished, the user must write UPDTIM and/or UPDCAL to 0 in the RTC\_CR.

The timing sequence of the time/calendar update is described in the figure below.

When entering the programming mode of the calendar fields, the time fields remain enabled and both the time and the calendar fields are stopped. This is due to the location of the calendar logical circuitry (downstream for low-power considerations). It is highly recommended to prepare all the fields to be updated before entering programming mode. In successive update operations, the user must wait for at least one second after resetting the UPDTIM/UPDCAL bit in the RTC\_CR before setting these bits again. This is done by waiting for the SEC flag in the RTC\_SR before setting the UPDTIM/UPDCAL bit. After resetting UPDTIM/UPDCAL, the SEC flag must also be cleared.

**27.5.7 RTC Accurate Clock Calibration**

The crystal oscillator that drives the RTC may not be as accurate as expected mainly due to temperature variation. The RTC is equipped with circuitry able to correct slow clock crystal drift.

To compensate for possible temperature variations over time, this accurate clock calibration circuitry can be programmed on-the-fly and also programmed during application manufacturing, in order to correct the crystal frequency accuracy at room temperature (20–25°C). The typical clock drift range at room temperature is ±20 ppm.

In the device operating temperature range, the 32.768 kHz crystal oscillator clock inaccuracy can be up to -200 ppm.

The RTC clock calibration circuitry allows positive or negative correction in a range of 1.5 ppm to 1950 ppm.

The calibration circuitry is fully digital. Thus, the configured correction is independent of temperature, voltage, process, etc., and no additional measurement is required to check that the correction is effective.

If the correction value configured in the calibration circuitry results from an accurate crystal frequency measure, the remaining accuracy is bounded by the values listed below:

- Below 1 ppm, for an initial crystal drift between 1.5 ppm up to 20 ppm, and from 30 ppm to 90 ppm
- Below 2 ppm, for an initial crystal drift between 20 ppm up to 30 ppm, and from 90 ppm to 130 ppm
- Below 5 ppm, for an initial crystal drift between 130 ppm up to 200 ppm

The calibration circuitry does not modify the 32.768 kHz crystal oscillator clock frequency but it acts by slightly modifying the 1 Hz clock period from time to time. The correction event occurs every  $1 + [(20 - (19 \times \text{HIGHPPM})) \times \text{CORRECTION}]$  seconds. When the period is modified, depending on the sign of the correction, the 1 Hz clock period increases or reduces by around 4 ms. Depending on the CORRECTION, NEGPPM and HIGHPPM values configured in RTC\_MR, the period interval between two correction events differs.

**Figure 27-4. Calibration Circuitry**

**Figure 27-5. Calibration Circuitry Waveforms**

The inaccuracy of a crystal oscillator at typical room temperature ( $\pm 20$  ppm at 20–25 °C) can be compensated if a reference clock/signal is used to measure such inaccuracy. This kind of calibration operation can be set up during the final product manufacturing by means of measurement equipment embedding such a reference clock. The correction of value must be programmed into the (RTC\_MR), and this value is kept as long as the circuitry is powered (backup area). Removing the backup power supply cancels this calibration. This room temperature calibration can be further processed by means of the networking capability of the target application.

To ease the comparison of the inherent crystal accuracy with the reference clock/signal during manufacturing, an internal prescaled 32.768 kHz clock derivative signal can be assigned to drive RTC output. To accommodate the measure, several clock frequencies can be selected among 1 Hz, 32 Hz, 64 Hz, 512 Hz.

The clock calibration correction drives the internal RTC counters but can also be observed in the RTC output when one of the following three frequencies 1 Hz, 32 Hz or 64 Hz is configured. The correction is not visible in the RTC output if 512 Hz frequency is configured.

**Note:** This adjustment does not consider the temperature variation.

The frequency drift (up to -200 ppm) due to temperature variation can be compensated using a reference time if the application can access such a reference. If a reference time cannot be used, a temperature sensor can be placed close to the crystal oscillator in order to get the operating temperature of the crystal oscillator. Once obtained, the temperature may be converted using a lookup table (describing the accuracy/temperature curve of the crystal oscillator used) and RTC\_MR configured accordingly. The calibration can be performed on-the-fly. This adjustment method is not based on a measurement of the crystal frequency/drift and therefore can be improved by means of the networking capability of the target application.

If no crystal frequency adjustment has been done during manufacturing, it is still possible to do it. In the case where a reference time of the day can be obtained through LAN/WAN network, it is possible to calculate the drift of the application crystal oscillator by comparing the values read on RTC Time Register (RTC\_TIMR) and programming the HIGHPPM and CORRECTION fields on RTC\_MR according to the difference measured between the reference time and those of RTC\_TIMR.

### 27.5.8 Waveform Generation

Waveforms can be generated in order to take advantage of the RTC inherent prescalers while the RTC is the only powered circuitry (Low-power mode of operation, Backup mode) or in any active mode. Entering Backup or Low-power operating modes does not affect the waveform generation outputs.

The outputs RTCOUT0 and RTCOUT1 can be configured to provide several types of waveforms. The figure below illustrates the different signals available to generate RTCOUT0 and RTCOUT1.

### 27.6.1 RTC Control Register

**Name:** RTC\_CR  
**Offset:** 0x00  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC\_WPMR).

|        |    |    |    |    |    |    |               |        |

#### Bits 17:16 – CALEVSEL[1:0] Calendar Event Selection

The event that generates the flag CALEV in RTC\_SR depends on the value of CALEVSEL

| Value | Name  | Description  |
|-------|-------|--|
| 0     | WEEK  | Week change (every Monday at time 00:00:00)            |
| 1     | MONTH | Month change (every 01 of each month at time 00:00:00) |
| 2     | YEAR  | Year change (every January 1 at time 00:00:00)         |
| 3     | YEAR  | Reserved   |

#### Bits 9:8 – TIMEVSEL[1:0] Time Event Selection

The event that generates the flag TIMEV in RTC\_SR depends on the value of TIMEVSEL.

| Value | Name     | Description           |
|-------|----------|-----------------------|
| 0     | MINUTE   | Minute change         |
| 1     | HOURL    | Hour change           |
| 2     | MIDNIGHT | Every day at midnight |
| 3     | NOON     | Every day at noon     |

#### Bit 1 – UPDCAL Update Request Calendar Register

Calendar counting consists of day, date, month, year and century counters. Calendar counters can be programmed once this bit is set and acknowledged by the bit ACKUPD of the RTC\_SR.

| Value | Description   |
|-------|---|
| 0     | No effect or, if UPDCAL has been previously written to 1, stops the update procedure. |
| 1     | Stops the RTC calendar counting.  |

#### Bit 0 – UPDTIM Update Request Time Register

Time counting consists of second, minute and hour counters. Time counters can be programmed once this bit is set and acknowledged by the bit ACKUPD of the RTC\_SR.

**SAM E70/S70/V70/V71**  
**Real-time Clock (RTC)**

---

---

| <b>Value</b> | <b>Description</b>  |
|--------------|---|
| 0            | No effect or, if UPDTIM has been previously written to 1, stops the update procedure. |
| 1            | Stops the RTC time counting.  |

### 27.6.2 RTC Mode Register

**Name:** RTC\_MR  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC\_WPMR).

|        |     |     |                 |     |     |     |     |     |  |

| Reset  |     |     |                 | 0   |     |     | 0   | 0   |  |

#### Bits 29:28 – TPERIOD[1:0] Period of the Output Pulse

| Value | Name    | Description |
|-------|---------|-------------|
| 0     | P_1S    | 1 second    |
| 1     | P_500MS | 500 ms      |
| 2     | P_250MS | 250 ms      |
| 3     | P_125MS | 125 ms      |

#### Bits 26:24 – THIGH[2:0] High Duration of the Output Pulse

| Value | Name    | Description  |
|-------|---------|--------------|
| 0     | H_31MS  | 31.2 ms      |
| 1     | H_16MS  | 15.6 ms      |
| 2     | H_4MS   | 3.91 ms      |
| 3     | H_976US | 976 $\mu$ s  |
| 4     | H_488US | 488 $\mu$ s  |
| 5     | H_122US | 122 $\mu$ s  |
| 6     | H_30US  | 30.5 $\mu$ s |
| 7     | H_15US  | 15.2 $\mu$ s |

#### Bits 22:20 – OUT1[2:0] RTCOUT1 Output Source Selection

| Value | Name         | Description                          |
|-------|--------------|--------------------------------------|
| 0     | NO_WAVE      | No waveform, stuck at '0'            |
| 1     | FREQ1HZ      | 1 Hz square wave                     |
| 2     | FREQ32HZ     | 32 Hz square wave                    |
| 3     | FREQ64HZ     | 64 Hz square wave                    |
| 4     | FREQ512HZ    | 512 Hz square wave                   |
| 5     | ALARM_TOGGLE | Output toggles when alarm flag rises |

| Value | Name       | Description                        |
|-------|------------|------------------------------------|
| 6     | ALARM_FLAG | Output is a copy of the alarm flag |
| 7     | PROG_PULSE | Duty cycle programmable pulse      |

### Bits 18:16 – OUT0[2:0] RTCOUT0 Output Source Selection

| Value | Name         | Description                          |
|-------|--------------|--------------------------------------|
| 0     | NO_WAVE      | No waveform, stuck at '0'            |
| 1     | FREQ1HZ      | 1 Hz square wave                     |
| 2     | FREQ32HZ     | 32 Hz square wave                    |
| 3     | FREQ64HZ     | 64 Hz square wave                    |
| 4     | FREQ512HZ    | 512 Hz square wave                   |
| 5     | ALARM_TOGGLE | Output toggles when alarm flag rises |
| 6     | ALARM_FLAG   | Output is a copy of the alarm flag   |
| 7     | PROG_PULSE   | Duty cycle programmable pulse        |

### Bit 15 – HIGHPPM HIGH PPM Correction

If the absolute value of the correction to be applied is lower than 30 ppm, it is recommended to clear HIGHPPM. HIGHPPM set to 1 is recommended for 30 ppm correction and above.

#### Formula:

If HIGHPPM = 0, then the clock frequency correction range is from 1.5 ppm up to 98 ppm. The RTC accuracy is less than 1 ppm for a range correction from 1.5 ppm up to 30 ppm.

The correction field must be programmed according to the required correction in ppm; the formula is as follows:

$$\text{CORRECTION} = \frac{3906}{20 \times \text{ppm}} - 1$$

The value obtained must be rounded to the nearest integer prior to being programmed into CORRECTION field.

If HIGHPPM = 1, then the clock frequency correction range is from 30.5 ppm up to 1950 ppm. The RTC accuracy is less than 1 ppm for a range correction from 30.5 ppm up to 90 ppm.

The correction field must be programmed according to the required correction in ppm; the formula is as follows:

$$\text{CORRECTION} = \frac{3906}{\text{ppm}} - 1$$

The value obtained must be rounded to the nearest integer prior to be programmed into CORRECTION field.

If NEGPPM is set to 1, the ppm correction is negative (used to correct crystals that are faster than the nominal 32.768 kHz).

| Value | Description   |
|-------|---|
| 0     | Lower range ppm correction with accurate correction.  |
| 1     | Higher range ppm correction with accurate correction. |

### Bits 14:8 – CORRECTION[6:0] Slow Clock Correction

| Value | Description   |
|-------|---|
| 0     | No correction   |
| 1-127 | The slow clock will be corrected according to the formula given in HIGHPPM description. |

### Bit 4 – NEGPPM Negative PPM Correction

See CORRECTION and HIGHPPM field descriptions.

NEGPPM must be cleared to correct a crystal slower than 32.768 kHz.

| Value | Description   |
|-------|---|
| 0     | Positive correction (the divider will be slightly higher than 32768). |
| 1     | Negative correction (the divider will be slightly lower than 32768).  |

### Bit 1 – PERSIAN PERSIAN Calendar

| Value | Description         |
|-------|---------------------|
| 0     | Gregorian calendar. |
| 1     | Persian calendar.   |

### Bit 0 – HRMOD 12-/24-hour Mode

| Value | Description               |
|-------|---------------------------|
| 0     | 24-hour mode is selected. |

**SAM E70/S70/V70/V71**  
**Real-time Clock (RTC)**

---

---

| Value | Description               |
|-------|---------------------------|
| 1     | 12-hour mode is selected. |

### 27.6.3 RTC Time Register

**Name:** RTC\_TIMR  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |    |          |            |     |     |     |     |     |  |
|--------|-----|----|----------|------------|-----|-----|-----|-----|-----|--|
|        | Bit | 31 | 30       | 29         | 28  | 27  | 26  | 25  | 24  |  |
|        |     |    |          |            |     |     |     |     |     |  |
| Access |     |    |          |            |     |     |     |     |     |  |
| Reset  |     |    |          |            |     |     |     |     |     |  |
|        |     |    |          |            |     |     |     |     |     |  |
|        | Bit | 23 | 22       | 21         | 20  | 19  | 18  | 17  | 16  |  |

| Reset  |     |    | 0        | 0          | 0   | 0   | 0   | 0   | 0   |  |
|        |     |    |          |            |     |     |     |     |     |  |
|        | Bit | 15 | 14       | 13         | 12  | 11  | 10  | 9   | 8   |  |
|        |     |    | MIN[6:0] |            |     |     |     |     |     |  |
| Access |     |    | R/W      | R/W        | R/W | R/W | R/W | R/W | R/W |  |
| Reset  |     |    | 0        | 0          | 0   | 0   | 0   | 0   | 0   |  |
|        |     |    |          |            |     |     |     |     |     |  |
|        | Bit | 7  | 6        | 5          | 4   | 3   | 2   | 1   | 0   |  |
|        |     |    | SEC[6:0] |            |     |     |     |     |     |  |
| Access |     |    | R/W      | R/W        | R/W | R/W | R/W | R/W | R/W |  |
| Reset  |     |    | 0        | 0          | 0   | 0   | 0   | 0   | 0   |  |

**Bit 22 – AMPM** Ante Meridiem Post Meridiem Indicator

This bit is the AM/PM indicator in 12-hour mode.

| Value | Description |
|-------|-------------|
| 0     | AM.         |
| 1     | PM.         |

**Bits 21:16 – HOURL[5:0]** Current Hour

The range that can be set is 1–12 (BCD) in 12-hour mode or 0–23 (BCD) in 24-hour mode.

**Bits 14:8 – MIN[6:0]** Current Minute

The range that can be set is 0–59 (BCD).

The lowest four bits encode the units. The higher bits encode the tens.

**Bits 6:0 – SEC[6:0]** Current Second

The range that can be set is 0–59 (BCD).

The lowest four bits encode the units. The higher bits encode the tens.

### 27.6.4 RTC Calendar Register

**Name:** RTC\_CALR  
**Offset:** 0x0C  
**Reset:** 0x01E11320  
**Property:** Read/Write

|        |     |           |     |     |            |     |     |     |     |

**Bits 29:24 – DATE[5:0]** Current Day in Current Month  
 The range that can be set is 01–31 (BCD).  
 The lowest four bits encode the units. The higher bits encode the tens.

**Bits 23:21 – DAY[2:0]** Current Day in Current Week  
 The range that can be set is 1–7 (BCD).  
 The coding of the number (which number represents which day) is user-defined as it has no effect on the date counter.

**Bits 20:16 – MONTH[4:0]** Current Month  
 The range that can be set is 01–12 (BCD).  
 The lowest four bits encode the units. The higher bits encode the tens.

**Bits 15:8 – YEAR[7:0]** Current Year  
 The range that can be set is 00–99 (BCD).  
 The lowest four bits encode the units. The higher bits encode the tens.

**Bits 6:0 – CENT[6:0]** Current Century  
 The range that can be set is 19–20 (Gregorian) or 13–14 (Persian) (BCD).  
 The lowest four bits encode the units. The higher bits encode the tens.

### 27.6.5 RTC Time Alarm Register

**Name:** RTC\_TIMALR  
**Offset:** 0x10  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC\_WPMR).

To change one of the SEC, MIN, HOUR fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to the RTC\_TIMALR. The first access clears the enable corresponding to the field to change (SECEN, MINEN, HOUREN). If the field is already cleared, this access is not required. The second access performs the change of the value (SEC, MIN, HOUR). The third access is required to re-enable the field by writing 1 in SECEN, MINEN, HOUREN fields.

|        |        |     |          |     |           |     |     |     |

| Reset  | 0      | 0   | 0        | 0   | 0         | 0   | 0   | 0   |

#### Bit 23 – HOUREN Hour Alarm Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | The hour-matching alarm is disabled. |
| 1     | The hour-matching alarm is enabled.  |

#### Bit 22 – AMPM AM/PM Indicator

This field is the alarm field corresponding to the BCD-coded hour counter.

#### Bits 21:16 – HOUR[5:0] Hour Alarm

This field is the alarm field corresponding to the BCD-coded hour counter.

#### Bit 15 – MINEN Minute Alarm Enable

| Value | Description                            |
|-------|--|
| 0     | The minute-matching alarm is disabled. |
| 1     | The minute-matching alarm is enabled.  |

#### Bits 14:8 – MIN[6:0] Minute Alarm

This field is the alarm field corresponding to the BCD-coded minute counter.

#### Bit 7 – SECEN Second Alarm Enable

# SAM E70/S70/V70/V71

## Real-time Clock (RTC)

| Value | Description                            |
|-------|--|
| 0     | The second-matching alarm is disabled. |
| 1     | The second-matching alarm is enabled.  |

### Bits 6:0 – SEC[6:0] Second Alarm

This field is the alarm field corresponding to the BCD-coded second counter.

### 27.6.6 RTC Calendar Alarm Register

**Name:** RTC\_CALALR  
**Offset:** 0x14  
**Reset:** 0x01010000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the System Controller Write Protection Mode Register (SYSC\_WPMR).

To change one of the DATE, MONTH fields, it is recommended to disable the field before changing the value and then re-enable it after the change has been made. This requires up to three accesses to the RTC\_CALALR. The first access clears the enable corresponding to the field to change (DATEEN, MTHEN). If the field is already cleared, this access is not required. The second access performs the change of the value (DATE, MONTH). The third access is required to re-enable the field by writing 1 in DATEEN, MTHEN fields.

|        |        |    |            |     |     |     |     |     |
|--------|--------|----|------------|-----|-----|-----|-----|-----|
| Bit    | 31     | 30 | 29         | 28  | 27  | 26  | 25  | 24  |
|        | DATEEN |    | DATE[5:0]  |     |     |     |     |     |
| Access | R/W    |    | R/W        | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0      |    | 0          | 0   | 0   | 0   | 0   | 1   |
|        |        |    |            |     |     |     |     |     |
| Bit    | 23     | 22 | 21         | 20  | 19  | 18  | 17  | 16  |
|        | MTHEN  |    | MONTH[4:0] |     |     |     |     |     |
| Access | R/W    |    | R/W        | R/W | R/W | R/W | R/W | R/W |
| Reset  | 0      |    | 0          | 0   | 0   | 0   | 0   | 1   |
|        |        |    |            |     |     |     |     |     |
| Bit    | 15     | 14 | 13         | 12  | 11  | 10  | 9   | 8   |
| Access |        |    |            |     |     |     |     |     |
| Reset  |        |    |            |     |     |     |     |     |
|        |        |    |            |     |     |     |     |     |
| Bit    | 7      | 6  | 5          | 4   | 3   | 2   | 1   | 0   |
| Access |        |    |            |     |     |     |     |     |
| Reset  |        |    |            |     |     |     |     |     |

#### Bit 31 – DATEEN Date Alarm Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | The date-matching alarm is disabled. |
| 1     | The date-matching alarm is enabled.  |

#### Bits 29:24 – DATE[5:0] Date Alarm

This field is the alarm field corresponding to the BCD-coded date counter.

#### Bit 23 – MTHEN Month Alarm Enable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | The month-matching alarm is disabled. |
| 1     | The month-matching alarm is enabled.  |

#### Bits 20:16 – MONTH[4:0] Month Alarm

This field is the alarm field corresponding to the BCD-coded month counter.

### 27.6.7 RTC Status Register

**Name:** RTC\_SR  
**Offset:** 0x18  
**Reset:** 0x00000000  
**Property:** Read-only

|        |     |    |    |       |       |       |     |       |        |
|--------|-----|----|----|-------|-------|-------|-----|-------|--------|
|        | Bit | 31 | 30 | 29    | 28    | 27    | 26  | 25    | 24     |
|        |     |    |    |       |       |       |     |       |        |
| Access |     |    |    |       |       |       |     |       |        |
| Reset  |     |    |    |       |       |       |     |       |        |
|        |     |    |    |       |       |       |     |       |        |
|        | Bit | 23 | 22 | 21    | 20    | 19    | 18  | 17    | 16     |
|        |     |    |    |       |       |       |     |       |        |
| Access |     |    |    |       |       |       |     |       |        |
| Reset  |     |    |    |       |       |       |     |       |        |
|        |     |    |    |       |       |       |     |       |        |
|        | Bit | 15 | 14 | 13    | 12    | 11    | 10  | 9     | 8      |
|        |     |    |    |       |       |       |     |       |        |
| Access |     |    |    |       |       |       |     |       |        |
| Reset  |     |    |    |       |       |       |     |       |        |
|        |     |    |    |       |       |       |     |       |        |
|        | Bit | 7  | 6  | 5     | 4     | 3     | 2   | 1     | 0      |
|        |     |    |    | TDERR | CALEV | TIMEV | SEC | ALARM | ACKUPD |
| Access |     |    |    | R     | R     | R     | R   | R     | R      |
| Reset  |     |    |    | 0     | 0     | 0     | 0   | 0     | 0      |

#### Bit 5 – TDERR Time and/or Date Free Running Error

| Value | Name         | Description  |
|-------|--------------|--|
| 0     | CORRECT      | The internal free running counters are carrying valid values since the last read of the Status Register (RTC_SR).                                |
| 1     | ERR_TIMEDATE | The internal free running counters have been corrupted (invalid date or time, non-BCD values) since the last read and/or they are still invalid. |

#### Bit 4 – CALEV Calendar Event

The calendar event is selected in the CALEVSEL field in the Control Register (RTC\_CR) and can be any one of the following events: week change, month change and year change.

| Value | Name        | Description  |
|-------|-------------|--|
| 0     | NO_CALEVENT | No calendar event has occurred since the last clear.           |
| 1     | CALEVENT    | At least one calendar event has occurred since the last clear. |

#### Bit 3 – TIMEV Time Event

The time event is selected in the TIMEVSEL field in the Control Register (RTC\_CR) and can be any one of the following events: minute change, hour change, noon, midnight (day change).

| Value | Name        | Description  |
|-------|-------------|--|
| 0     | NO_TIMEVENT | No time event has occurred since the last clear.           |
| 1     | TIMEVENT    | At least one time event has occurred since the last clear. |

#### Bit 2 – SEC Second Event

| Value | Name        | Description  |
|-------|-------------|--|
| 0     | NO_SECEVENT | No second event has occurred since the last clear.           |
| 1     | SECEVENT    | At least one second event has occurred since the last clear. |

#### Bit 1 – ALARM Alarm Flag

| Value | Name          | Description                           |
|-------|---------------|---------------------------------------|
| 0     | NO_ALARMEVENT | No alarm matching condition occurred. |

# SAM E70/S70/V70/V71

## Real-time Clock (RTC)

---

---

| Value | Name       | Description                               |
|-------|------------|---|
| 1     | ALARMEVENT | An alarm matching condition has occurred. |

**Bit 0 – ACKUPD** Acknowledge for Update

| Value | Name    | Description                                    |
|-------|---------|--|
| 0     | FREERUN | Time and calendar registers cannot be updated. |
| 1     | UPDATE  | Time and calendar registers can be updated.    |

### 27.6.8 RTC Status Clear Command Register

**Name:** RTC\_SCCR  
**Offset:** 0x1C  
**Reset:** –  
**Property:** Write-only

|        |     |    |    |          |        |        |        |        |        |
|--------|-----|----|----|----------|--------|--------|--------|--------|--------|

|        | Bit | 7  | 6  | 5        | 4      | 3      | 2      | 1      | 0      |
|        |     |    |    | TDERRCLR | CALCLR | TIMCLR | SECCLR | ALRCLR | ACKCLR |
| Access |     |    |    | W        | W      | W      | W      | W      | W      |
| Reset  |     |    |    | –        | –      | –      | –      | –      | –      |

#### Bit 5 – TDERRCLR Time and/or Date Free Running Error Clear

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Clears corresponding status flag in the Status Register (RTC_SR). |

#### Bit 4 – CALCLR Calendar Clear

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Clears corresponding status flag in the Status Register (RTC_SR). |

#### Bit 3 – TIMCLR Time Clear

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Clears corresponding status flag in the Status Register (RTC_SR). |

#### Bit 2 – SECCLR Second Clear

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Clears corresponding status flag in the Status Register (RTC_SR). |

#### Bit 1 – ALRCLR Alarm Clear

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Clears corresponding status flag in the Status Register (RTC_SR). |

#### Bit 0 – ACKCLR Acknowledge Clear

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Clears corresponding status flag in the Status Register (RTC_SR). |

### 27.6.9 RTC Interrupt Enable Register

**Name:** RTC\_IER  
**Offset:** 0x20  
**Reset:** –  
**Property:** Write-only

#### Bit 5 – TDERREN Time and/or Date Error Interrupt Enable

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | The time and date error interrupt is enabled. |

#### Bit 4 – CALEN Calendar Event Interrupt Enable

| Value | Description                                       |
|-------|---|
| 0     | No effect.  |
| 1     | The selected calendar event interrupt is enabled. |

#### Bit 3 – TIMEN Time Event Interrupt Enable

| Value | Description                                   |
|-------|---|
| 0     | No effect.                                    |
| 1     | The selected time event interrupt is enabled. |

#### Bit 2 – SECEN Second Event Interrupt Enable

| Value | Description                               |
|-------|---|
| 0     | No effect.                                |
| 1     | The second periodic interrupt is enabled. |

#### Bit 1 – ALREN Alarm Interrupt Enable

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | The alarm interrupt is enabled. |

#### Bit 0 – ACKEN Acknowledge Update Interrupt Enable

| Value | Description                                      |
|-------|--|
| 0     | No effect.                                       |
| 1     | The acknowledge for update interrupt is enabled. |

### 27.6.10 RTC Interrupt Disable Register

**Name:** RTC\_IDR  
**Offset:** 0x24  
**Reset:** –  
**Property:** Write-only

#### Bit 5 – TDERRDIS Time and/or Date Error Interrupt Disable

| Value | Description                                    |
|-------|--|
| 0     | No effect.                                     |
| 1     | The time and date error interrupt is disabled. |

#### Bit 4 – CALDIS Calendar Event Interrupt Disable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | The selected calendar event interrupt is disabled. |

#### Bit 3 – TIMDIS Time Event Interrupt Disable

| Value | Description                                    |
|-------|--|
| 0     | No effect.                                     |
| 1     | The selected time event interrupt is disabled. |

#### Bit 2 – SECDIS Second Event Interrupt Disable

| Value | Description                                |
|-------|--|
| 0     | No effect.                                 |
| 1     | The second periodic interrupt is disabled. |

#### Bit 1 – ALRDIS Alarm Interrupt Disable

| Value | Description                      |
|-------|----------------------------------|
| 0     | No effect.                       |
| 1     | The alarm interrupt is disabled. |

#### Bit 0 – ACKDIS Acknowledge Update Interrupt Disable

| Value | Description                                       |
|-------|---|
| 0     | No effect.  |
| 1     | The acknowledge for update interrupt is disabled. |

### 27.6.11 RTC Interrupt Mask Register

**Name:** RTC\_IMR  
**Offset:** 0x28  
**Reset:** 0x00000000  
**Property:** Read-only

|        |     |    |    |       |     |     |     |     |     |
|--------|-----|----|----|-------|-----|-----|-----|-----|-----|
|        | Bit | 31 | 30 | 29    | 28  | 27  | 26  | 25  | 24  |
|        |     |    |    |       |     |     |     |     |     |
| Access |     |    |    |       |     |     |     |     |     |
| Reset  |     |    |    |       |     |     |     |     |     |
|        |     |    |    |       |     |     |     |     |     |
|        | Bit | 23 | 22 | 21    | 20  | 19  | 18  | 17  | 16  |
|        |     |    |    |       |     |     |     |     |     |
| Access |     |    |    |       |     |     |     |     |     |
| Reset  |     |    |    |       |     |     |     |     |     |
|        |     |    |    |       |     |     |     |     |     |
|        | Bit | 15 | 14 | 13    | 12  | 11  | 10  | 9   | 8   |
|        |     |    |    |       |     |     |     |     |     |
| Access |     |    |    |       |     |     |     |     |     |
| Reset  |     |    |    |       |     |     |     |     |     |
|        |     |    |    |       |     |     |     |     |     |
|        | Bit | 7  | 6  | 5     | 4   | 3   | 2   | 1   | 0   |
|        |     |    |    | TDERR | CAL | TIM | SEC | ALR | ACK |
| Access |     |    |    | R     | R   | R   | R   | R   | R   |
| Reset  |     |    |    | 0     | 0   | 0   | 0   | 0   | 0   |

#### Bit 5 – TDERR Time and/or Date Error Mask

| Value | Description                                   |
|-------|---|
| 0     | The time and/or date error event is disabled. |
| 1     | The time and/or date error event is enabled.  |

#### Bit 4 – CAL Calendar Event Interrupt Mask

| Value | Description  |
|-------|--|
| 0     | The selected calendar event interrupt is disabled. |
| 1     | The selected calendar event interrupt is enabled.  |

#### Bit 3 – TIM Time Event Interrupt Mask

| Value | Description                                    |
|-------|--|
| 0     | The selected time event interrupt is disabled. |
| 1     | The selected time event interrupt is enabled.  |

#### Bit 2 – SEC Second Event Interrupt Mask

| Value | Description                                |
|-------|--|
| 0     | The second periodic interrupt is disabled. |
| 1     | The second periodic interrupt is enabled.  |

#### Bit 1 – ALR Alarm Interrupt Mask

| Value | Description                      |
|-------|----------------------------------|
| 0     | The alarm interrupt is disabled. |
| 1     | The alarm interrupt is enabled.  |

#### Bit 0 – ACK Acknowledge Update Interrupt Mask

| Value | Description                                       |
|-------|---|
| 0     | The acknowledge for update interrupt is disabled. |
| 1     | The acknowledge for update interrupt is enabled.  |

### 27.6.12 RTC Valid Entry Register

**Name:** RTC\_VER  
**Offset:** 0x2C  
**Reset:** 0x00000000  
**Property:** Read-only

#### Bit 3 – NVCALALR Non-valid Calendar Alarm

| Value | Description  |
|-------|--|
| 0     | No invalid data has been detected in RTC_CALALR (Calendar Alarm Register). |
| 1     | RTC_CALALR has contained invalid data since it was last programmed.        |

#### Bit 2 – NVTIMALR Non-valid Time Alarm

| Value | Description  |
|-------|--|
| 0     | No invalid data has been detected in RTC_TIMALR (Time Alarm Register). |
| 1     | RTC_TIMALR has contained invalid data since it was last programmed.    |

#### Bit 1 – NVCAL Non-valid Calendar

| Value | Description  |
|-------|--|
| 0     | No invalid data has been detected in RTC_CALR (Calendar Register). |
| 1     | RTC_CALR has contained invalid data since it was last programmed.  |

#### Bit 0 – NVTIM Non-valid Time

| Value | Description   |
|-------|---|
| 0     | No invalid data has been detected in RTC_TIMR (Time Register).    |
| 1     | RTC_TIMR has contained invalid data since it was last programmed. |

## 28. Real-time Timer (RTT)

### 28.1 Description

The Real-time Timer (RTT) is built around a 32-bit counter used to count roll-over events of the programmable 16-bit prescaler driven from the 32-kHz slow clock source. It generates a periodic interrupt and/or triggers an alarm on a programmed value.

The RTT can also be configured to be driven by the 1Hz RTC signal, thus taking advantage of a calibrated 1Hz clock.

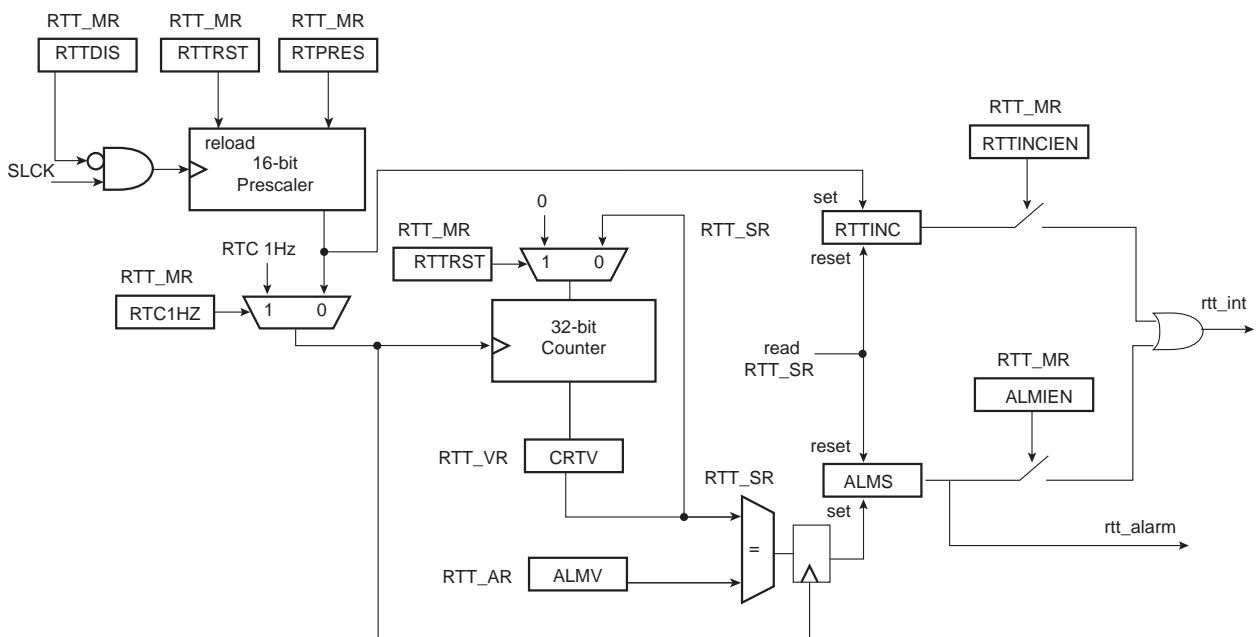

The slow clock source can be fully disabled to reduce power consumption when only an elapsed seconds count is required.

### 28.2 Embedded Characteristics

- 32-bit Free-running Counter on prescaled slow clock or RTC calibrated 1Hz clock
- 16-bit Configurable Prescaler
- Interrupt on Alarm or Counter Increment

### 28.3 Block Diagram

**Figure 28-1. Real-time Timer Block Diagram**

### 28.4 Functional Description

The programmable 16-bit prescaler value can be configured through the RTPRES field in the RTT Mode register (RTT\_MR).

Configuring the RTPRES field value to 0x8000 (default value) corresponds to feeding the real-time counter with a 1Hz signal (if the slow clock is 32.768 kHz). The 32-bit counter can count up to  $2^{32}$  seconds, corresponding to more than 136 years, then roll over to 0. Bit RTTINC in the RTT Status Register (RTT\_SR) is set each time there is a prescaler roll-over.

# SAM E70/S70/V70/V71

## Real-time Timer (RTT)

---

The real-time 32-bit counter can also be supplied by the 1Hz RTC clock. This mode is interesting when the RTC 1Hz is calibrated (CORRECTION field  $\neq$  0 in RTC\_MR) in order to guaranty the synchronism between RTC and RTT counters.

Setting the RTC1HZ bit in the RTT\_MR drives the 32-bit RTT counter from the 1Hz RTC clock. In this mode, the RTPRES field has no effect on the 32-bit counter.

The prescaler roll-over generates an increment of the real-time timer counter if RTC1HZ = 0. Otherwise, if RTC1HZ = 1, the RTT counter is incremented every second. The RTTINC bit is set independently from the 32-bit counter increment.

The RTT can also be used as a free-running timer with a lower time-base. The best accuracy is achieved by writing RTPRES to 3 in RTT\_MR.

Programming RTPRES to 1 or 2 is forbidden.

If the RTT is configured to trigger an interrupt, the interrupt occurs two slow clock cycles after reading the RTT\_SR. To prevent several executions of the interrupt handler, the interrupt must be disabled in the interrupt handler and re-enabled when the RTT\_SR is cleared.

The CRTV field can be read at any time in the RTT Value register (RTT\_VR). As this value can be updated asynchronously with the Host Clock, the CRTV field must be read twice at the same value to read a correct value.

The current value of the counter is compared with the value written in the RTT Alarm register (RTT\_AR). If the counter value matches the alarm, the ALMS bit in the RTT\_SR is set. The RTT\_AR is set to its maximum value (0xFFFFFFFF) after a reset.

The ALMS flag is always a source of the RTT alarm signal that may be used to exit the system from low power modes (see the Real-time Timer Block Diagram above).

The alarm interrupt must be disabled (ALMIEN must be cleared in RTT\_MR) when writing a new ALMV value in the RTT\_AR.

The RTTINC bit can be used to start a periodic interrupt, the period being one second when the RTPRES field value = 0x8000 and the slow clock = 32.768 kHz.

The RTTINCIEN bit must be cleared prior to writing a new RTPRES value in the RTT\_MR.

Reading the RTT\_SR automatically clears the RTTINC and ALMS bits.

Writing the RTTRST bit in the RTT\_MR immediately reloads and restarts the clock divider with the new programmed value. This also resets the 32-bit counter.

When not used, the RTT can be disabled in order to suppress dynamic power consumption in this module. This can be achieved by setting the RTTDIS bit in the RTT\_MR.

**Figure 28-2. RTT Counting**

## 28.5 Register Summary

| Offset | Name   | Bit Pos. | 7            | 6 | 5 | 4 | 3      | 2 | 1      | 0         |        |
|--------|--------|----------|--------------|---|---|---|--------|---|--------|-----------|--------|
| 0x00   | RTT_MR | 7:0      | RTPRES[7:0]  |   |   |   |        |   |        |           |        |

|        |        | 31:24    |              |   |   |   |        |   |        |           |        |

### 28.5.1 Real-time Timer Mode Register

**Name:** RTT\_MR  
**Offset:** 0x00  
**Reset:** 0x00008000  
**Property:** Read/Write

|        |     |              |     |     |        |     |     |        |           |        |
|--------|-----|--------------|-----|-----|--------|-----|-----|--------|-----------|--------|
|        | Bit | 31           | 30  | 29  | 28     | 27  | 26  | 25     | 24        |        |
|        |     |              |     |     |        |     |     |        | RTC1HZ    |        |
| Access |     |              |     |     |        |     |     |        | R/W       |        |
| Reset  |     |              |     |     |        |     |     |        | 0         |        |
|        | Bit | 23           | 22  | 21  | 20     | 19  | 18  | 17     | 16        |        |
|        |     |              |     |     | RTTDIS |     |     | RTTRST | RTTINCIEN | ALMIEN |
| Access |     |              |     |     | R/W    |     |     | R/W    | R/W       | R/W    |
| Reset  |     |              |     |     | 0      |     |     | 0      | 0         | 0      |
|        | Bit | 15           | 14  | 13  | 12     | 11  | 10  | 9      | 8         |        |
|        |     | RTPRES[15:8] |     |     |        |     |     |        |           |        |
| Access |     | R/W          | R/W | R/W | R/W    | R/W | R/W | R/W    | R/W       |        |
| Reset  |     | 1            | 0   | 0   | 0      | 0   | 0   | 0      | 0         |        |
|        | Bit | 7            | 6   | 5   | 4      | 3   | 2   | 1      | 0         |        |
|        |     | RTPRES[7:0]  |     |     |        |     |     |        |           |        |
| Access |     | R/W          | R/W | R/W | R/W    | R/W | R/W | R/W    | R/W       |        |
| Reset  |     | 0            | 0   | 0   | 0      | 0   | 0   | 0      | 0         |        |

#### Bit 24 – RTC1HZ Real-Time Clock 1Hz Clock Selection

| Value | Description  |
|-------|--|
| 0     | The RTT 32-bit counter is driven by the 16-bit prescaler roll-over events. |
| 1     | The RTT 32-bit counter is driven by the 1Hz RTC clock.                     |

#### Bit 20 – RTTDIS Real-time Timer Disable

| Value | Description   |
|-------|---|
| 0     | The RTT is enabled.                                 |
| 1     | The RTT is disabled (no dynamic power consumption). |

#### Bit 18 – RTTRST Real-time Timer Restart

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Reloads and restarts the clock divider with the new programmed value. This also resets the 32-bit counter. |

#### Bit 17 – RTTINCIEN Real-time Timer Increment Interrupt Enable

| Value | Description  |
|-------|--|
| 0     | The bit RTTINC in RTT_SR has no effect on interrupt. |
| 1     | The bit RTTINC in RTT_SR asserts interrupt.          |

#### Bit 16 – ALMIEN Alarm Interrupt Enable

| Value | Description  |
|-------|--|
| 0     | The bit ALMS in RTT_SR has no effect on interrupt. |
| 1     | The bit ALMS in RTT_SR asserts interrupt.          |

#### Bits 15:0 – RTPRES[15:0] Real-time Timer Prescaler Value

Defines the number of SLCK periods required to increment the RTT. The RTTINCIEN bit must be cleared prior to writing a new RTPRES value.

# SAM E70/S70/V70/V71

## Real-time Timer (RTT)

---

RTPRES is defined as follows:

- RTPRES = 0: The prescaler period is equal to  $2^{16}$  \* SLCK periods.
- RTPRES = 1 or 2: forbidden.
- RTPRES  $\neq$  0,1 or 2: The prescaler period is equal to RTPRES \* SLCK periods.

### 28.5.2 Real-time Timer Alarm Register

**Name:** RTT\_AR  
**Offset:** 0x04  
**Reset:** 0xFFFFFFFF  
**Property:** Read/Write

The alarm interrupt must be disabled (ALMIEN must be cleared in RTT\_MR) when writing a new ALMV value.

|        |     |             |     |     |     |     |     |     |     |
|--------|-----|-------------|-----|-----|-----|-----|-----|-----|-----|
|        | Bit | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  |
|        |     | ALMV[31:24] |     |     |     |     |     |     |     |
| Access |     | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 1           | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
|        |     |             |     |     |     |     |     |     |     |
|        | Bit | 23          | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|        |     | ALMV[23:16] |     |     |     |     |     |     |     |
| Access |     | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 1           | 1   | 1   | 1   | 1   | 1   | 1   | 1   |

| 1     | The Real-time Alarm occurred since the last read of RTT_SR.         |

## **29. General Purpose Backup Registers (GPBR)**

### **29.1 Description**

The System Controller embeds 128 bits of General Purpose Backup registers organized as 8 32-bit registers.

It is possible to generate an immediate clear of the content of General Purpose Backup registers 0 to 3 (first half) if a Low-power Debounce event is detected on one of the wakeup pins, WKUP0 or WKUP1. The content of the other General Purpose Backup registers (second half) remains unchanged.

The Supply Controller module must be programmed accordingly. In the register SUPC\_WUMR in the Supply Controller module, LPDBCCLR, LPDBCEN0 and/or LPDBCEN1 bit must be configured to 1 and LPDBC must be other than 0.

If a Tamper event has been detected, it is not possible to write to the General Purpose Backup registers while the LPBCS0 or LPBCS1 flags are not cleared in the Supply Controller Status Register (SUPC\_SR).

### **29.2 Embedded Characteristics**

- 128 bits of General Purpose Backup Registers
- Immediate Clear on Tamper Event

### 29.3 Register Summary

| Offset | Name      | Bit Pos. | 7                 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |  |

**Bits 31:0 – GPBR\_VALUE[31:0]** Value of GPBR x

If a Tamper event has been detected, it is not possible to write GPBR\_VALUE as long as the LPDBCS0 or LPDBCS1 flag has not been cleared in the Supply Controller Status Register (SUPC\_SR).

## **30. Clock Generator**

### **30.1 Description**

The Clock Generator user interface is embedded within the Power Management Controller and is described in Power Management Controller (PMC) User Interface. However, the Clock Generator registers are named CKGR\_.

### **30.2 Embedded Characteristics**

The Clock Generator is comprised of the following:

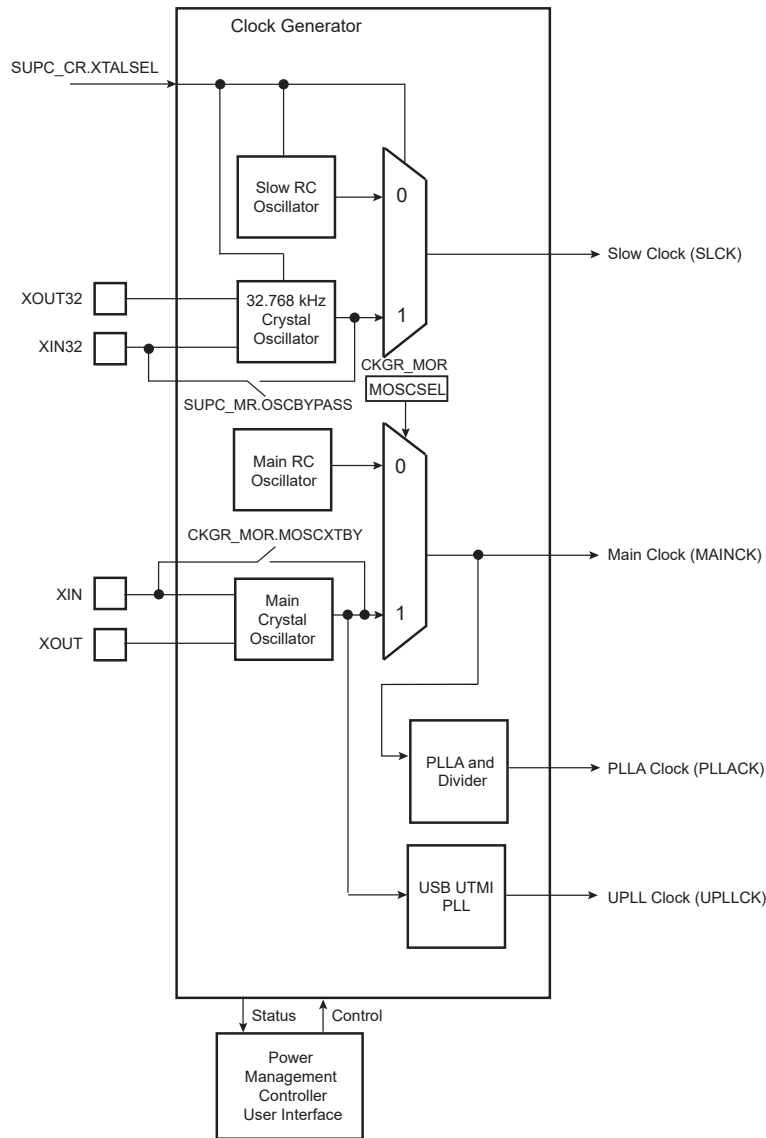

- A low-power 32.768 kHz crystal oscillator with Bypass mode
- A low-power Slow RC oscillator (32 kHz typical)
- A 3 to 20 MHz Main crystal oscillator with Bypass mode
- A Main RC oscillator. Three output frequencies can be selected: 4/8/12 MHz. By default 12 MHz is selected. 8 MHz and 12 MHz are factory-trimmed.
- A 480 MHz UTMI PLL, providing a clock for the USB high-speed controller
- A 160 to 500 MHz programmable PLL (input from 8 to 32 MHz)

It provides the following clocks:

- SLCK — Slow clock. The only permanent clock within the system
- MAINCK — output of the Main clock oscillator selection: either the Main crystal oscillator or Main RC oscillator
- PLLACK — output of the divider and 160 to 500 MHz programmable PLL (PLLA)
- UPLLCK — output of the 480 MHz UTMI PLL (UPLL)

### 30.3 Block Diagram

Figure 30-1. Clock Generator Block Diagram

### 30.4 Slow Clock

The Supply Controller embeds a slow clock generator that is supplied with the VDDIO power supply. As soon as VDDIO is supplied, both the 32.768 kHz crystal oscillator and the Slow RC oscillator are powered, but only the Slow RC oscillator is enabled. This allows the Slow clock (SLCK) to be valid in a short time (about 100  $\mu$ s).

SLCK is generated either by the 32.768 kHz crystal oscillator or by the Slow RC oscillator.

To select the clock source, the selection is made via the XTALSEL bit in the Supply Controller Control Register (SUPC\_CR).

#### 30.4.1 Slow RC Oscillator (32 kHz typical)

By default, the Slow RC oscillator is enabled and selected as a source of SLCK.

Compared to the 32.768 kHz crystal oscillator, this oscillator offers a faster startup time and is less exposed to the external environment, as it is fully integrated. However, its output frequency is subject to larger variations with supply voltage, temperature and manufacturing process. Therefore, the user must take these variations into account when this oscillator is used as a time base (startup counter, frequency monitor, etc.). Refer to the section “Electrical Characteristics”.

This oscillator is disabled by clearing the SUPC\_CR.XTALSEL.

### Related Links

## 30.4.2 32.768 kHz Crystal Oscillator

By default, the 32.768 kHz oscillator is disabled. To use this oscillator, the XIN32 and XOUT32 pins must be connected to a 32.768 kHz crystal or to a ceramic resonator. Refer to the section “Electrical Characteristics” for appropriate loading capacitors selection on XIN32 and XOUT32.

Note that the user is not obliged to use the 32.768 kHz crystal oscillator and can use the Slow RC oscillator instead. Using the 32.768 kHz crystal oscillator provides a more accurate frequency than the Slow RC oscillator.

To select the 32.768 kHz crystal oscillator as the source of SLCK, the bit SUPC\_CR.XTALSEL must be set. This results in a sequence which first configures the PIO lines multiplexed with XIN32 and XOUT32 to be driven by the crystal oscillator, then enables the 32.768 kHz crystal oscillator and then disables the Slow RC oscillator to save power. The switch of SLCK source is glitch-free.

Reverting to the Slow RC oscillator is only possible by shutting down the VDDIO power supply. If the user does not need the 32.768 kHz crystal oscillator, the XIN32 and XOUT32 pins can be left unconnected since by default the XIN32 and XOUT32 system I/O pins are in PIO input mode with pullup after reset.

The user can also set the 32.768 kHz crystal oscillator in Bypass mode instead of connecting a crystal. In this case, the user must provide the external clock signal on XIN32. For input characteristics of the XIN32 pin, refer to the section “Electrical Characteristics”. To enter Bypass mode, the OSCBYPASS bit of the Supply Controller Mode register (SUPC\_MR) must be set prior to setting SUPC\_CR.XTALSEL.

## 30.5 Main Clock

The Main clock (MAINCK) has two sources:

- A Main RC oscillator (4/8/12 MHz) with a fast startup time and that is selected by default to start the system
- A Main crystal oscillator with Bypass mode

**Figure 30-2. Main Clock (MAINCK) Block Diagram**

### 30.5.1 Main RC Oscillator

After reset, the Main RC oscillator is enabled with the 12 MHz frequency selected. This oscillator is selected as the source of MAINCK. MAINCK is the default clock selected to start the system.

Only the 8/12 MHz RC oscillator frequencies are calibrated in production. Refer to the section “Electrical Characteristics”.

The software can disable or enable the Main RC oscillator with the MOSCRSEN bit in the Clock Generator Main Oscillator Register (CKGR\_MOR).

The output frequency of the Main RC oscillator can be selected among 4, 8 or 12 MHz. Selection is done by configuring the field MOSCRCF in CKGR\_MOR. When changing the frequency selection, the MOSCRCS bit in the Power Management Controller Status Register (PMC\_SR) is automatically cleared and MAINCK is stopped until the oscillator is stabilized. Once the oscillator is stabilized, MAINCK restarts and PMC\_SR.MOSCRCS is set. Note that enabling the Main RC oscillator (MOSCRSEN = 1) and changing its frequency (MOSCRCF) at the same time is not allowed.

This oscillator must be enabled first and its frequency changed in a second step.

When disabling the Main RC oscillator by clearing the CKGR\_MOR.MOSCRSEN bit, the PMC\_SR.MOSCRCS bit is automatically cleared, indicating that the oscillator is OFF.

Setting the MOSCRCS bit in the Power Management Controller Interrupt Enable Register (PMC\_IER) triggers an interrupt to the processor.

[58. Electrical Characteristics for SAM E70/S70](#)

### 30.5.2 Main RC Oscillator Frequency Adjustment

The 8 MHz and 12 MHz frequencies are factory-centered to the typical values by using Flash calibration bits (refer to the “Electrical Characteristics” chapter).

The Flash calibration bits setting the Main RC oscillator frequency to 8 MHz and 12 MHz vary from device to device. To get a starting point when changing the CAL8 or CAL12 fields, it is recommended to first read their corresponding Flash calibration bits in the Flash Controller.

The user can adjust the value of the Main RC oscillator frequency by modifying the trimming values done in production on 8 MHz and 12 MHz. This may be used to compensate frequency drifts due to temperature or voltage. The values stored in the Flash cannot be erased by a Flash erase command or by the ERASE signal. Values written by the user application in the Oscillator Calibration Register (PMC\_OCR) are reset after each power-up or peripheral reset.

By default, SEL4/SEL8/SEL12 are cleared, so the Main RC oscillator is driven with the factory-programmed Flash calibration bits which are programmed during chip production.

**Note:** These factory-programmed calibration bitfields can be read through the EEFC using the *Get CALIB bit command* (GCALB).

In order to calibrate the oscillator lower frequency, SEL4 must be set to '1' and a valid frequency value must be configured in CAL4. Likewise, SEL8/12 must be set to '1' and a trim value must be configured in CAL8/12 in order to adjust the other frequencies of the oscillator.

It is possible to adjust the oscillator frequency while operating from this oscillator. For example, when running on lowest frequency, it is possible to change the CAL4 value if SEL4 is set in PMC\_OCR.

At any time, the user can measure the main RC oscillator output frequency by means of the Main Frequency Counter (refer to "[Main Frequency Counter](#)"). Once the frequency measurement is done, the main RC oscillator calibration field (CALx) can be adjusted accordingly to correct this oscillator output frequency.

[58. Electrical Characteristics for SAM E70/S70](#)

### 30.5.3 Main Crystal Oscillator

After reset, the Main crystal oscillator is disabled and is not selected as the source of MAINCK.

As the source of MAINCK, the Main crystal oscillator provides a very precise frequency. The software enables or disables this oscillator in order to reduce power consumption through CKGR\_MOR.MOSCXTEN.

When disabling this oscillator by clearing the CKGR\_MOR.MOSCXTEN, PMC\_SR.MOSCXTS is automatically cleared, indicating the oscillator is off.

When enabling this oscillator, the user must initiate the startup time counter. The startup time depends on the characteristics of the external device connected to this oscillator.

When CKGR\_MOR.MOSCXTEN and CKGR\_MOR.MOSCXTST are written to enable this oscillator, the PIO lines multiplexed with XIN and XOUT are driven by the Main crystal oscillator. PMC\_SR.MOSCXTS is cleared and the counter starts counting down on SLCK divided by 8 from the CKGR\_MOR.MOSCXTST value. Because the CKGR\_MOR.MOSCXTST value is coded with 8 bits, the startup time can be programmed up to 2048 SLCK periods, corresponding to about 62 ms when running at 32.768 kHz.

When the startup time counter reaches '0', PMC\_SR.MOSCXTS is set, indicating that the oscillator is stabilized. Setting the MOSCXTS bit in the Interrupt Mask Register (PMC\_IMR) can trigger an interrupt to the processor.

### 30.5.4 Main Clock Source Selection

The source of MAINCK can be selected from the following:

- The Main RC oscillator
- The Main crystal oscillator
- An external clock signal provided on the XIN input (Bypass mode of the Main crystal oscillator)

The advantage of the Main RC oscillator is its fast startup time. By default, this oscillator is selected to start the system and it must be selected prior to entering Wait mode.

The advantage of the Main crystal oscillator is its high level of accuracy.

The selection of the oscillator is made with bit CKGR\_MOR.MOSCSEL. The switchover of the MAINCK source is glitch-free, so there is no need to run MCK out of SLCK, PLLACK or UPLLCK in order to change the selection. PMC\_SR.MOSCSELS indicates when the switch sequence is done.

Setting PMC\_IMR.MOSCSELS triggers an interrupt to the processor.

#### MAINCK Switching Sequence

When switching the Main Clock MAINCK source from the Main Crystal oscillator to the Main RC oscillator it is mandatory to follow the below steps:

- Start the Main RC oscillator and keep MAINCK on the Main Crystal Oscillator (this step is optional at startup as it is the default configuration)

- Switch MAINCK to the Main RC oscillator and keep the Main Crystal Oscillator on
- Switch off the Main Crystal Oscillator is a third separate step

### 30.5.5 Bypassing the Main Crystal Oscillator

Prior to bypassing the Main crystal oscillator, the external clock frequency provided on the XIN pin must be stable and within the values specified in the XIN Clock characteristics in the section “Electrical Characteristics”.

The sequence is as follows:

1. Ensure that an external clock is connected on XIN.
2. Enable the bypass by setting CKGR\_MOR.MOSCXTBY.
3. Disable the Main crystal oscillator by clearing CKGR\_MOR.MOSCXTEN.

### 30.5.6 Main Frequency Counter

The Main frequency counter measures the Main RC oscillator and the Main crystal oscillator against the SLCK and is managed by CKGR\_MCFR.

During the measurement period, the Main frequency counter increments at the speed of the clock defined by the bit CKGR\_MCFR.CCSS.

A measurement is started in the following cases:

- When CKGR\_MCFR.RCMEAS is written to ‘1’.
- When the Main RC oscillator is selected as the source of MAINCK and when this oscillator is stable (i.e., when the MOSCRCS bit is set)
- When the Main crystal oscillator is selected as the source of MAINCK and when this oscillator is stable (i.e., when the MOSCXTS bit is set)
- When MAINCK source selection is modified

The measurement period ends at the 16th falling edge of SLCK, the MAINFRDY bit in CKGR\_MCFR is set and the counter stops counting. Its value can be read in the MAINF field of CKGR\_MCFR and gives the number of clock cycles during 16 periods of SLCK, so that the frequency of the Main RC oscillator or Main crystal oscillator can be determined.

If switching the source of MAINCK to the Main crystal oscillator from the Main RC oscillator, follow the programming sequence below to ensure that the oscillator is present and that its frequency is valid:

1. Enable the Main crystal oscillator by setting CKGR\_MOR.MOSCXTEN. Configure the CKGR\_MOR.MOSCXTST field with the Main crystal oscillator startup time as defined in the section “Electrical Characteristics”.
2. Wait for PMC\_SR.MOSCXTS flag to rise, indicating the end of a startup period of the Main crystal oscillator.
3. Select the Main crystal oscillator as the source clock of the Main frequency counter by setting CKGR\_MCFR.CCSS.
4. Initiate a frequency measurement by setting CKGR\_MCFR.RCMEAS.
5. Read CKGR\_MCFR.MAINFRDY until its value equals 1.
6. Read CKGR\_MCFR.MAINF and compute the value of the Main crystal frequency.

If the MAINF value is valid, software can switch MAINCK to the Main crystal oscillator. Refer to ["Main Clock Source Selection"](#).

**Figure 30-3. Main Frequency Counter Block Diagram**

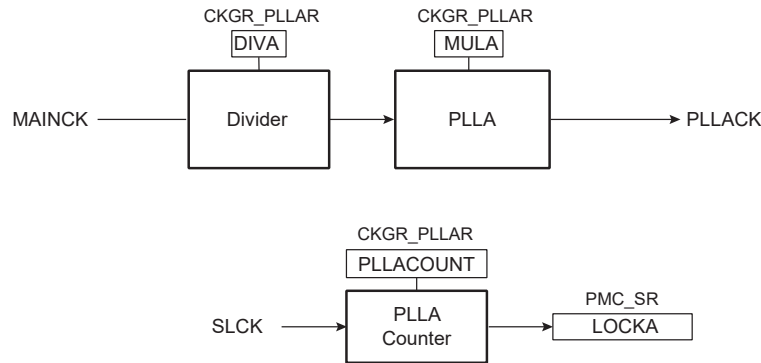

### 30.6 PLLA Clock

The PLLA clock (PLLACK) is generated from MAINCK by the PLLA and a predivider. This combination allows a wide range of frequencies to be selected on either MCK, HCLK or the PCKx outputs.

The following figure shows the block diagram of the dividers and PLLA blocks.

**Figure 30-4. Divider and PLLA Block Diagram**

#### 30.6.1 Divider and Phase Lock Loop Programming

The divider can be set between 1 and 255 in steps of 1. When a divider field (DIV) is cleared, the output of the corresponding divider and the PLL output is a continuous signal at level 0. On reset, each DIV field is cleared, thus the corresponding PLL input clock is stuck at '0'.

The PLL (PLLA) allows multiplication of the divider's outputs. The PLL clock signal has a frequency that depends on the respective source signal frequency and on the parameters DIV (DIVA) and MUL (MULA). The factor applied to the source signal frequency is  $(MUL + 1)/DIV$ . When MUL is written to '0' or DIV = 0, the PLL is disabled and its power consumption is saved. Note that there is a delay of two SLCK clock cycles between the disable command and the real disable of the PLL. Re-enabling the PLL can be performed by writing a value higher than '0' in the MUL field and DIV higher than '0'.

Whenever the PLL is re-enabled or one of its parameters is changed, the LOCK (LOCKA) bit in PMC\_SR is automatically cleared. The values written in the PLLCOUNT field (PLLACOUNT) in CKGR\_PLLR (CKGR\_PLLAR) are loaded in the PLL counter. The PLL counter then decrements at the speed of SLCK until it reaches '0'. At this time, PMC\_SR.LOCK is set and can trigger an interrupt to the processor. The user has to load the number of SLCK cycles required to cover the PLL transient time into the PLLCOUNT field.

To avoid programming the PLL with a multiplication factor that is too high, the user can saturate the multiplication factor value sent to the PLL by setting the PLLA\_MMAX field in the PLL Maximum Multiplier Value Register (PMC\_PMMR).

It is forbidden to change the MAINCK characteristics (oscillator selection, frequency adjustment of the Main RC oscillator) when:

- MAINCK is selected as the PLLA clock source, and
- MCK is sourced from PLLA.

To change the MAINCK characteristics, the user must:

1. Switch the MCK source to MAINCK by writing a '1' to PMC\_MCKR.CSS.
2. Change the Main RC oscillator frequency (MOSCRCF) or oscillator selection (MOSCSEL) in CKGR\_MOR.
3. Wait for MOSCRCS (if frequency changes) or MOSCSELS (if oscillator selection changes) in PMC\_SR.
4. Disable and then enable the PLL.
5. Wait for the LOCK flag in PMC\_SR.
6. Switch back MCK to the PLLA by writing the appropriate value to PMC\_MCKR.CSS.

### 30.7 UTMI PLL Clock

The source of the UTMI PLL (UPLL) is the Main Crystal oscillator. The UPLL provides the UTMI PLL Clock (UPLLCK) and UPLLCKDIV clock signals.

The UPLL has two possible multiplying factors: x40 and x30. To generate UPLLCK at 480 MHz (typical USB case), this leads to two possible crystal oscillator frequencies: 12 or 16 MHz. The crystal oscillator frequency (12 or 16 MHz) must be programmed in UTMI\_CKTRIM.FREQ prior to enabling the UPLL.

When the UPLL is enabled by writing a '1' to bit UPLEN in the UTMI Clock Register (CKGR\_UCKR), the LOCKU bit in PMC\_SR is automatically cleared. The values written in the PLLCOUNT field in CKGR\_UCKR are loaded in the UTMI PLL counter. The UTMI PLL counter then decrements at the speed of SLCK divided by 8 until it reaches '0'. At this time, the LOCKU bit is set in PMC\_SR and can trigger an interrupt to the processor. The user has to load the number of SLCK cycles required to cover the UTMI PLL transient time into the PLLCOUNT field.

**Figure 30-5. UTMI PLL Block Diagram**

## **31. Power Management Controller (PMC)**

### **31.1 Description**

The Power Management Controller (PMC) optimizes power consumption by controlling all system and user peripheral clocks. The PMC enables/disables the clock inputs to many of the peripherals and the Cortex-M7 processor.

The Supply Controller selects either the Slow RC oscillator or the 32.768 kHz crystal oscillator as the source of SLCK. The unused oscillator is disabled automatically so that power consumption is optimized.

By default, at startup, the chip runs out of MCK using the Main RC oscillator running at 12 MHz.

### **31.2 Embedded Characteristics**

The Power Management Controller provides the following clocks:

- Host Clock (MCK), programmable from a few hundred Hz to the maximum operating frequency of the device. It is available to the modules running permanently, such as the Enhanced Embedded Flash Controller
- Processor Clock (HCLK), automatically switched off when entering the processor in Sleep mode
- Free-running processor Clock (FCLK)
- The Cortex-M7 SysTick external clock
- USB Clock (USB\_48M), required by the USB peripheral
- Peripheral Clocks with independent ON/OFF control, provided to the peripherals
- Programmable Clock Outputs (PCKx), selected from the clock generator outputs to drive the device PCK pins
- Clock sources independent of MCK and HCLK, provided by internal PCKx for USART, UART, TC, Embedded Trace Macrocell (ETM) and CAN Clocks
- Generic Clock (GCLK) with controllable division and ON/OFF control, independent of MCK and HCLK. Provided to selected peripherals.

The Power Management Controller also provides the following features on clocks:

- A Main crystal oscillator failure detector
- A 32.768 kHz crystal oscillator frequency monitor
- A frequency counter on Main crystal oscillator or Main RC oscillator
- An on-the-fly adjustable Main RC oscillator frequency

### 31.3 Block Diagram

Figure 31-1. General Clock Distribution Block Diagram

### 31.4 Host Clock Controller

The Host Clock Controller provides the Host Clock (MCK) with the selection and division of the clock generator's output signals. MCK is the source clock of the peripheral clocks.

The clock to be selected between SLCK, MAINCK, PLLACK and UPLLCKDIV is configured in PMC\_MCKR.CSS. The prescaler supports the 1, 2, 3, 4, 8, 16, 32, 64 division factors and is configured using PMC\_MCKR.PRES.

Each time PMC\_MCKR is configured to define a new MCK, the MCKRDY bit is cleared in PMC\_SR. It reads '0' until MCK is established. Then, the MCKRDY bit is set and can trigger an interrupt to the processor. This feature is useful when switching from a high-speed clock to a lower one to inform the software when the change is completed.

**Note:** Users cannot modify MDIV and CSS at the same access. Each field must be modified separately with a wait for the MCKRDY flag between the first field modification and the second field modification.

### 31.5 Processor Clock Controller

The PMC features a Processor Clock (HCLK) Controller that implements the processor Sleep mode. HCLK can be disabled by executing the WFI (WaitForInterrupt) or the WFE (WaitForEvent) processor instruction while the LPM bit is at '0' in the PMC Fast Startup Mode register (PMC\_FSMR).

HCLK is enabled after a reset and is automatically re-enabled by any enabled interrupt. The processor Sleep mode is entered by disabling HCLK, which is automatically re-enabled by any enabled fast or normal interrupt, or by the reset of the product.

When processor Sleep mode is entered, the current instruction is finished before the clock is stopped, but this does not prevent data transfers from other hosts of the system bus.

### 31.6 SysTick External Clock

When the processor selects the SysTick external clock, the calibration value is fixed to 150000. This allows the generation of a time base of 1 ms with the SysTick clock at the maximum frequency on HCLK divided by 2.

The SysTick counter may miss a number of counts if an external clock source is selected when entering the sleep mode.

Refer to the section “Arm Cortex-M7 Processor” for details on selecting the SysTick external clock.

### Related Links

[15. Arm Cortex-M7](#)

## 31.7 USB Full-speed Clock Controller

The user can select the PLLA or the UPLL output as the USB FS clock (USB\_48M) by writing a ‘1’ to the USBS bit in the USB Clock Register (PMC\_USB). The user then must program the corresponding PLL to generate an appropriate frequency depending on the USBDIV bit in PMC\_USB.

When PMC\_SR.LOCKA and PMC\_SR.LOCKU are set to ‘1’, the PLLA and UPLL are stable. Then, USB\_48M can be enabled by setting the USBCLK bit in the System Clock Enable register (PMC\_SCER). To save power on this peripheral when not used, the user can set the USBCLK bit in the System Clock Disable register (PMC\_SCDR). The USBCLK bit in the System Clock Status register (PMC\_SCSR) gives the status of this clock. The USB port requires both the USB clock signal and the peripheral clock. The USB peripheral clock is controlled by means of the Host Clock Controller.

## 31.8 Core and Bus Independent Clocks for Peripherals

The following table lists the peripherals that require a PCKx clock to operate while the core, bus and peripheral clock frequencies are modified, thus providing communications at a bit rate which is independent for the core/bus/peripheral clock. This mode of operation is possible by using the internally generated independent clock sources.

Internal clocks can be independently selected between SLCK, MAINCK, any available PLL clock, and MCK by configuring PMC\_PCKx.CSS. The independent clock sources can be also divided by configuring PMC\_PCKx.PRES.

Each internal clock signal (PCKx) can be enabled and disabled by writing a ‘1’ to the corresponding PMC\_SCER.PCKx and PMC\_SCDR.PCKx, respectively. The status of the internal clocks are given in PMC\_SCSR.PCKx.

The status flag PMC\_SR.PCKRDYx indicates that the programmable internal clock has been programmed in the Programmable clock registers.

The independent clock source must also be selected in each peripheral in the Clock Assignments table to operate communications, timings, etc without influencing the frequency of the core/bus/peripherals (except frequency limitations listed in each peripheral).

**Table 31-1. Clock Assignments**

| Clock Name | Peripheral        |
|------------|-------------------|
| PCK3       | ETM               |
| PCK4       | UARTx/USARTx      |
| PCK5       | MCANx             |
| PCK6       | TC0.Ch1...TC3.Ch2 |
| PCK7       | TC0.Ch0           |

**Note:** USB, GMAC and MLB do not require PCKx to operate independently of core and bus peripherals.

## 31.9 Peripheral and Generic Clock Controller

The PMC controls the clocks of the embedded peripherals by means of the Peripheral Control register (PMC\_PCR). With this register, the user can enable and disable the different clocks used by the peripherals:

- Peripheral clocks (periph\_clk[PID]), routed to every peripheral and derived from the Host clock (MCK), and
- Generic clocks (GCLK[PID]), routed to I2SC0 and I2SC1. These clocks are independent of the core and bus clocks (HCLK, MCK and periph\_clk[PID]). They are generated by selection and division of the following sources: SLCK, MAINCK, UPLLCKDIV, PLLACK and MCK. Refer to the description of each peripheral for the limitation to be applied to GCLK[PID] compared to periph\_clk[PID].

To configure a peripheral's clocks, PMC\_PCR.CMD must be written to '1' and PMC\_PCR.PID must be written with the index of the corresponding peripheral. All other configuration fields must be correctly set.

To read the current clock configuration of a peripheral, PMC\_PCR.CMD must be written to '0' and PMC\_PCR.PID must be written with the index of the corresponding peripheral regardless of the values of other fields. This write does not modify the configuration of the peripheral. The PMC\_PCR can then be read to know the configuration status of the corresponding PID.

The user can also enable and disable these clocks by configuring the Peripheral Clock Enable (PMC\_PCERx) and Peripheral Clock Disable (PMC\_PCDRx) registers. The status of the peripheral clock activity can be read in the Peripheral Clock Status registers (PMC\_PCSRx).

When a peripheral or a generic clock is disabled, it is immediately stopped. These clocks are disabled after a reset.

To stop a peripheral clock, it is recommended that the system software wait until the peripheral has executed its last programmed operation before disabling the clock. This is to avoid data corruption or erroneous behavior of the system.

The bit number in PMC\_PCERx, PMC\_PCDRx, and PMC\_PCSRx is the Peripheral Identifier defined at the product level. The bit number corresponds to the interrupt source number assigned to the peripheral.

## 31.10 Asynchronous Partial Wakeup

### 31.10.1 Description

The asynchronous partial wakeup wakes up a peripheral in a fully asynchronous way when activity is detected on the communication line. The asynchronous partial wakeup function automatically manages the peripheral clock. It reduces overall power consumption of the system by clocking peripherals only when needed.

Asynchronous partial wakeup can be enabled in Wait mode (SleepWalking), or in Active mode.

Only the following peripherals can be configured with asynchronous partial wakeup: UARTx and TWIHSx.

The peripheral selected for asynchronous partial wakeup must first be configured so that its clock is enabled. To do so, write a '1' to the appropriate PIDx bit in PMC\_PCER registers.

### 31.10.2 Asynchronous Partial Wakeup in Wait Mode (SleepWalking)

When the system is in Wait mode, all clocks of the system except SLCK are stopped. When an asynchronous clock request from a peripheral occurs, the PMC partially wakes up the system to feed the clock only to this peripheral. The rest of the system is not fed with the clock, thus optimizing power consumption. Finally, depending on user-configurable conditions, the peripheral either wakes up the whole system if these conditions are met or stops the peripheral clock until the next clock request. If a wakeup request occurs, SleepWalking is automatically disabled until the user instructs the PMC to enable SleepWalking. This is done by writing a '1' to PIDx in the PMC SleepWalking Enable register (PMC\_SLPWK\_ER).

**Figure 31-2. SleepWalking Waveforms**

### 31.10.2.1 Configuration Procedure

Before configuring SleepWalking for a peripheral, check that the PIDx bit in PMC\_PCSR is set. This ensures that the peripheral clock is enabled.

The steps to enable SleepWalking for a peripheral are the following:

1. Check that the corresponding PIDx bit in the PMC SleepWalking Activity Status register (PMC\_SLPWK\_ASR) is set to '0'. This ensures that the peripheral has no activity in progress.
2. Enable SleepWalking for the peripheral by writing a '1' to the corresponding PIDx bit in the PMC\_SLPWK\_ER.
3. Check that the corresponding PIDx bit in PMC\_SLPWK\_ASR is set to '0'. This ensures that no activity has started during the enable phase.
4. In the PMC\_SLPWK\_ASR, if the corresponding PIDx bit is set, SleepWalking must be immediately disabled by writing a '1' to the PIDx bit in the PMC SleepWalking Disable register (PMC\_SLPWK\_DR). Wait for the end of peripheral activity before reinitializing the procedure.

If the corresponding PIDx bit is set to '0', then the peripheral clock is disabled and the system can then be placed in Wait mode.

Before entering Wait mode, check that the AIP bit in the PMC SleepWalking Activity In Progress Register (PMC\_SLPWK\_AIPR) is cleared. This ensures that none of the peripherals is currently active.

**Note:** When SleepWalking for a peripheral is enabled and the core is running (system not in Wait mode), the peripheral must not be accessed before a wakeup of the peripheral is performed.

### 31.10.3 Asynchronous Partial Wakeup in Active Mode

When the system is in Active mode, peripherals enabled for asynchronous partial wakeup have their respective clocks stopped until the peripherals request a clock. When a peripheral requests the clock, the PMC provides the clock without processor intervention.

The triggering of the peripheral clock request depends on conditions which can be configured for each peripheral. If these conditions are met, the peripheral asserts a request to the PMC. The PMC disables the Asynchronous Partial Wakeup mode of the peripheral and provides the clock to the peripheral until the user instructs the PMC to re-enable partial wakeup on the peripheral. This is done by setting PMC\_SLPWK\_ER.PIDx.

If the conditions are not met, the peripheral clears the clock request and the PMC stops the peripheral clock until the clock request is reasserted by the peripheral.

**Note:** Configuring Asynchronous Partial Wake-up mode requires the same registers as Sleep-Walking mode.

**Figure 31-3. Asynchronous Partial Wake-up in Active Mode**

### 31.10.3.1 Configuration Procedure

Before configuring the asynchronous partial wakeup function of a peripheral, check that the PIDx bit in PMC\_PCSR is set. This ensures that the peripheral clock is enabled.

The steps to enable the asynchronous partial wakeup function of a peripheral are the following:

1. Check that the corresponding PIDx bit in the PMC SleepWalking Activity Status register (PMC\_SLPWK\_ASR) is set to '0'. This ensures that the peripheral has no activity in progress.
2. Enable the asynchronous partial wakeup function of the peripheral by writing a '1' to the corresponding PIDx bit in the PMC\_SLPWK\_ER.
3. Check that the corresponding PIDx bit in PMC\_SLPWK\_ASR is set to '0'. This ensures that no activity has started during the enable phase.

If an activity has started during the enable phase, the asynchronous partial wakeup function must be immediately disabled by writing a '1' to the PIDx bit in the PMC SleepWalking Disable register (PMC\_SLPWK\_DR). Wait for the end of peripheral activity before reinitializing the procedure.

## 31.11 Free-running Processor Clock

The free-running Processor clock (FCLK) used for sampling interrupts and clocking debug blocks ensures that interrupts can be sampled, and sleep events can be traced, while the processor is sleeping.

## 31.12 Programmable Clock Output Controller

The PMC controls three signals to be output on the external pins PCKx. Each signal can be independently programmed via the Programmable Clock registers (PMC\_PCKx).

PCKx can be independently selected between SLCK, MAINCK, PLLACK, UPLLCKDIV and MCK by configuring PMC\_PCKx.CSS. Each output signal can also be divided by 1 to 256 by configuring PMC\_PCKx.PRES.

Each output signal can be enabled and disabled by writing a '1' to the corresponding bits PMC\_SCER.PCKx and PMC\_SCDR.PCKx, respectively. The status of the active programmable output clocks is given in PMC\_SCSR.PCKx.

The status flag PMC\_SR.PCKRDYx indicates that PCKx is actually what has been programmed in registers PMC\_PCKx.

As the Programmable Clock Controller does not manage with glitch prevention when switching clocks, it is strongly recommended to disable PCKx before any configuration change and to re-enable it after the change is performed.

## 31.13 Fast Startup

At exit from Wait mode, the device allows the processor to restart in several microseconds only if the C-code function that manages the Wait mode entry and exit is linked to and executed from on-chip SRAM.

The fast startup time cannot be achieved if the first instruction after an exit is located in the embedded Flash.

If fast startup is not required, or if the first instruction after exit from Wait mode is located in embedded Flash, see ["Startup from Embedded Flash"](#).

To instruct the device to enter Wait mode, refer to section “Power Considerations”.

A fast startup occurs upon the detection of a programmed level on one of the 14 wakeup inputs (WKUP) or upon an active alarm from the RTC, RTT and USB Controller. The polarity of each of the 14 wakeup inputs is programmable in the PMC Fast Startup Polarity Register (PMC\_FSPR).

**WARNING** The duration of the WKUPx pins active level must be greater than four MAINCK cycles.

The fast startup circuitry, as shown in the following figure, is fully asynchronous and provides a fast startup signal to the PMC. As soon as the fast startup signal is asserted, the Main RC oscillator restarts automatically.

When entering Wait mode, the embedded Flash can be placed in one of the low-power modes (Deep-powerdown or Standby mode) with PMC\_FSMR.FLPM. FLPM can be configured at any time and its value will be applied to the next Wait mode period.

The power consumption reduction is optimal when PMC\_FSMR.FLPM is configured to ‘1’ (Deep-powerdown mode). If the field is configured to ‘0’ (Standby mode), the power consumption is slightly higher than in Deep-powerdown mode.

When PMC\_FSMR.FLPM is configured to ‘2’, the Wait mode Flash power consumption is equivalent to that of the Active mode when there is no read access on the Flash.

**Figure 31-4. Fast Startup Circuitry**

Each wakeup input pin and alarm can be enabled to generate a fast startup event by setting the corresponding bit in PMC\_FSMR.

The user interface does not provide any status for fast startup. The status can be read in the PIO Controller and the status registers of the RTC, RTT and USB Controller.

**Related Links**

[7. Power Considerations](#)

### 31.14 Startup from Embedded Flash

The inherent startup time of the embedded Flash cannot provide a fast startup of the system.

If system fast startup time is not required, the first instruction after a Wait mode exit can be located in the embedded Flash. Under these conditions, prior to entering Wait mode, the Flash controller must be programmed to perform access in 0 wait-state (refer to the embedded Flash controller section).

The procedure and conditions to enter Wait mode and the circuitry to exit Wait mode are strictly the same as fast startup (see "Fast Startup").

**Related Links**

### 31.15 Main Crystal Oscillator Failure Detection

The Main crystal oscillator failure detector monitors the Main crystal oscillator against the Slow RC oscillator and provides an automatic switchover of the MAINCK source to the Main RC oscillator in case of failure detection.

The failure detector can be enabled or disabled by configuring the CKGR\_MOR.CFDEN, and it can also be disabled in either of the following cases:

- After a VDDCORE reset
- When the Main crystal oscillator is disabled (MOSCXTEN = 0)

A failure is detected by means of a counter incrementing on the Main crystal oscillator output and detection logic is triggered by the Slow RC oscillator which is automatically enabled when CFDEN = 1.

The counter is cleared when the Slow RC oscillator clock signal is low and enabled when the signal is high. Thus, the failure detection time is one Slow RC oscillator period. If, during the high level period of the Slow RC oscillator clock signal, less than eight Main crystal oscillator clock periods have been counted, then a failure is reported. Note that when enabling the failure detector, up to two cycles of the Slow RC oscillator are needed to detect a failure of the Main crystal oscillator.

If a failure of Main crystal oscillator is detected, PMC\_SR.CFDEV and PMC\_SR.FOS both indicate a failure event. PMC\_SR.CFDEV is cleared on read of PMC\_SR, and PMC\_SR.FOS is cleared by writing a '1' to the FOCLR bit in the PMC Fault Output Clear Register (PMC\_FOCR).

Only PMC\_SR.CFDEV can generate an interrupt if the corresponding interrupt source is enabled in PMC\_IER. The current status of the clock failure detection can be read at any time from PMC\_SR.CFDS.

**Figure 31-5. Clock Failure Detection Example**

Note: Ratio of clock periods is for illustration purposes only.

If the Main crystal oscillator is selected as the source clock of MAINCK (CKGR\_MOR.MOSCSEL = 1), and if the MCK source is PLLACK or UPLLCKDIV (CSS = 2 or 3), a clock failure detection automatically forces MAINCK to be the source clock for MCK. Then, regardless of the PMC configuration, a clock failure detection automatically forces

the Main RC oscillator to be the source clock for MAINCK. If the Main RC oscillator is disabled when a clock failure detection occurs, it is automatically re-enabled by the clock failure detection mechanism.

Two Slow RC oscillator clock cycles are necessary to detect and switch from the Main crystal oscillator to the Main RC oscillator if the source of MCK is MAINCK, or three Slow RC oscillator clock cycles if the source of MCK is PLLACK or UPLLCKDIV.

A clock failure detection activates a fault output that is connected to the Pulse Width Modulator (PWM) Controller. With this connection, the PWM controller is able to force its outputs and to protect the driven device, if a clock failure is detected.

### 31.16 32.768 kHz Crystal Oscillator Frequency Monitor

The frequency of the 32.768 kHz crystal oscillator can be monitored by means of logic driven by the Main RC oscillator known as a reliable clock source. This function is enabled by configuring the XT32KFME bit of CKGR\_MOR. Prior to enabling this frequency monitor, the 32.768 kHz crystal oscillator must be started and its startup time be elapsed. Refer to details on the Slow clock generator in the section “Supply Controller (SUPC)”.

An error flag (XT32KERR in PMC\_SR) is asserted when the 32.768 kHz crystal oscillator frequency is out of the  $\pm 10\%$  nominal frequency value (i.e., 32.768 kHz). The error flag can be cleared only if the frequency monitor is disabled.

When the Main RC oscillator frequency is set to 4 MHz, the accuracy of the measurement is  $\pm 40\%$  as this frequency is not trimmed during production. Therefore,  $\pm 10\%$  accuracy is obtained only if the Main RC oscillator frequency is configured for 8 or 12 MHz.

The monitored clock frequency is declared invalid if at least 4 consecutive clock period measurement results are over the nominal period  $\pm 10\%$ . Note that modifying the trimming values of the Main RC oscillator (PMC\_OCR) may impact the monitor accuracy and lead to inappropriate failure detection.

Due to the possible frequency variation of the Main RC oscillator acting as reference clock for the monitor logic, any 32.768 kHz crystal frequency deviation over  $\pm 10\%$  of the nominal frequency is systematically reported as an error by means of PMC\_SR.XT32KERR. Between  $-1\%$  and  $-10\%$  and  $+1\%$  and  $+10\%$ , the error is not systematically reported.

Thus only a crystal running at 32.768 kHz frequency ensures that the error flag will not be asserted. The permitted drift of the crystal is 10000 ppm (1%), which allows any standard crystal to be used.

If the Main RC oscillator frequency range needs to be changed while the frequency monitor is operating, the monitoring must be stopped prior to change the Main RC oscillator frequency. Then it can be re-enabled as soon as PMC\_SR.MOSCRCSS is set.

The error flag can be defined as an interrupt source of the PMC by setting PMC\_IER.XT32KERR. This flag is also routed to the RSTC and may generate a reset of the device.

#### Related Links

[23. Supply Controller \(SUPC\)](#)

### 31.17 Recommended Programming Sequence

Follow the steps below to program the PMC:

1. If the Main crystal oscillator is not required, the PLL and divider can be directly configured ([Step 6.](#)) else this oscillator must be started ([Step 2.](#)).
2. Enable the Main crystal oscillator by setting CKGR\_MOR.MOSCXTEN. The user can define a startup time. This can be done by configuring the appropriate value in CKGR\_MOR.MOSCXTST. Once this register has been correctly configured, the user must wait for PMC\_SR.MOSCXTS to be set. This can be done either by polling PMC\_SR.MOSCXTS, or by waiting for the interrupt line to be raised if the associated interrupt source (MOSCXTS) has been enabled in PMC\_IER.
3. Switch MAINCK to the Main crystal oscillator by setting CKGR\_MOR.MOSCSEL.
4. Wait for PMC\_SR.MOSCSELS to be set to ensure the switch is complete.
5. Check MAINCK frequency:  
This frequency can be measured via CKGR\_MCFR.

Read CKGR\_MCFR until the MAINFRDY field is set, after which the user can read CKGR\_MCFR.MAINF by performing an additional read. This provides the number of Main clock cycles that have been counted during a period of 16 SLCK cycles.

If MAINF = 0, switch MAINCK to the Main RC Oscillator by clearing CKGR\_MOR.MOSCSEL. If MAINF ≠ 0, proceed to [Step 6](#).

6. Set PLLA and Divider (if not required, proceed to [Step 7](#)):

All parameters needed to configure PLLA and the divider are located in CKGR\_PLLAR.

CKGR\_PLLAR.DIVA is used to control the divider. This parameter can be programmed between 0 and 127. Divider output is divider input divided by DIVA parameter. By default, DIVA field is cleared which means that the divider and PLLA are turned off.

CKGR\_PLLAR.MULA is the PLLA multiplier factor. This parameter can be programmed between 0 and 62. If MULA is cleared, PLLA will be turned off, otherwise the PLLA output frequency is PLLA input frequency multiplied by (MULA + 1).

CKGR\_PLLAR.PLLACOUNT specifies the number of SLCK cycles before PMC\_SR.LOCKA is set after CKGR\_PLLAR has been written.

Once CKGR\_PLLAR has been written, the user must wait for PMC\_SR.LOCKA to be set. This can be done either by polling PMC\_SR.LOCKA or by waiting for the interrupt line to be raised if the associated interrupt source (LOCKA) has been enabled in PMC\_IER. All fields in CKGR\_PLLAR can be programmed in a single write operation. If MULA or DIVA is modified, the LOCKA bit goes low to indicate that PLLA is not yet ready. When PLLA is locked, LOCKA is set again. The user must wait for the LOCKA bit to be set before using the PLLA output clock.

7. Select MCK and HCLK:

MCK and HCLK are configurable via PMC\_MCKR.

CSS is used to select the clock source of MCK and HCLK. By default, the selected clock source is MAINCK.

PRES is used to define the HCLK and MCK prescaler. The user can choose between different values (1, 2, 3, 4, 8, 16, 32, 64). Prescaler output is the selected clock source frequency divided by the PRES value.

MDIV is used to define the MCK divider. It is possible to choose between different values (0, 1, 2, 3). MCK output is the HCLK frequency divided by 1, 2, 3 or 4, depending on the value programmed in MDIV.

By default, MDIV is cleared, which indicates that the HCLK is equal to MCK.

Once the PMC\_MCKR has been written, the user must wait for PMC\_SR.MCKRDY to be set. This can be done either by polling PMC\_SR.MCKRDY or by waiting for the interrupt line to be raised if the associated interrupt source (MCKRDY) has been enabled in PMC\_IER. PMC\_MCKR must not be programmed in a single write operation. The programming sequence for PMC\_MCKR is as follows:

If a new value for PMC\_MCKR.CSS corresponds to any of the available PLL clocks:

- a. Program PMC\_MCKR.PRES.
- b. Wait for PMC\_SR.MCKRDY to be set.
- c. Program PMC\_MCKR.MDIV.
- d. Wait for PMC\_SR.MCKRDY to be set.
- e. Program PMC\_MCKR.CSS.
- f. Wait for PMC\_SR.MCKRDY to be set.

If a new value for PMC\_MCKR.CSS corresponds to MAINCK or SLCK:

- a. Program PMC\_MCKR.CSS.
- b. Wait for PMC\_SR.MCKRDY to be set.
- c. Program PMC\_MCKR.PRES.
- d. Wait for PMC\_SR.MCKRDY to be set.

If CSS, MDIV or PRES are modified at any stage, the MCKRDY bit goes low to indicate that MCK and HCLK are not yet ready. The user must wait for MCKRDY bit to be set again before using MCK and HCLK.

**Note:** If PLLA clock was selected as MCK and the user decides to modify it by writing a new value into CKGR\_PLLAR, the MCKRDY flag will go low while PLLA is unlocked. Once PLLA is locked again, LOCKA goes high and MCKRDY is set. While PLLA is unlocked, MCK selection is automatically changed to SLCK for PLLA. For further information, see "[Clock Switching Waveforms](#)".

MCK is MAINCK divided by 2.

8. Select the Programmable clocks (PCKx):  
PCKx are controlled via registers PMC\_SCER, PMC\_SCDR and PMC\_SCSR.

PCKx can be enabled and/or disabled via PMC\_SCER and PMC\_SCDR. Three PCKx can be used. PMC\_SCSR indicates which PCKx is enabled. By default all PCKx are disabled.

PMC\_PCKx registers are used to configure PCKx.

PMC\_PCKx.CSS is used to select the PCKx divider source. Several clock options are available:

- MAINCK
- SLCK
- MCK
- PLLACK
- UPLLCKDIV

SLCK is the default clock source.

PMC\_PCKx.PRES is used to control the PCKx prescaler. It is possible to choose between different values (1 to 256). PCKx output is prescaler input divided by PRES. By default, the PRES value is cleared which means that PCKx is equal to Slow clock.

Once PMC\_PCKx has been configured, the corresponding PCKx must be enabled and the user must wait for PMC\_SR.PCKRDYx to be set. This can be done either by polling PMC\_SR.PCKRDYx or by waiting for the interrupt line to be raised if the associated interrupt source (PCKRDYx) has been enabled in PMC\_IER. All parameters in PMC\_PCKx can be programmed in a single write operation.

If the PMC\_PCKx.CSS and PMC\_PCKx.PRES parameters are to be modified, the corresponding PCKx must be disabled first. The parameters can then be modified. Once this has been done, the user must re-enable PCKx and wait for the PCKRDYx bit to be set.

9. Enable the peripheral clocks  
Once all of the previous steps have been completed, the peripheral clocks can be enabled and/or disabled via registers PMC\_PCERx and PMC\_PCDRx.

## 31.18 Clock Switching Details

### 31.18.1 Host Clock Switching Timings

The following two tables, [Clock Switching Timings \(Worst Case\)](#) and [Clock Switching Timings Between Two PLLs \(Worst Case\)](#) give the worst case timings required for MCK to switch from one selected clock to another one. This is in the event that the prescaler is deactivated. When the prescaler is activated, an additional time of 64 clock cycles of the newly selected clock has to be added.

**Table 31-2. Clock Switching Timings (Worst Case)**

| From   | MAINCK                       | SLCK                       | PLL Clock                                   |
|--------|------------------------------|----------------------------|---|
| To     |                              |                            |   |
| MAINCK | –                            | 4 x SLCK +<br>2.5 x MAINCK | 3 x PLL Clock +<br>4 x SLCK +<br>1 x MAINCK |
| SLCK   | 0.5 x MAINCK +<br>4.5 x SLCK | –                          | 3 x PLL Clock +<br>5 x SLCK                 |

.....continued

| From      | MAINCK  | SLCK  | PLL Clock                |
|-----------|---|---|--------------------------|
| PLL Clock | $0.5 \times \text{MAINCK} +$<br>$4 \times \text{SLCK} +$<br>$\text{PLLCOUNT} \times \text{SLCK} +$<br>$2.5 \times \text{PLL Clock}$ | $2.5 \times \text{PLL Clock} +$<br>$5 \times \text{SLCK} +$<br>$\text{PLLCOUNT} \times \text{SLCK}$ | See the following table. |

**Notes:**

1. PLL designates any available PLL of the Clock Generator.
2. PLLCOUNT designates either PLLACOUNT or UPLLCOUNT.

**Table 31-3. Clock Switching Timings Between Two PLLs (Worst Case)**

|           | From | PLLACK   | UPLL Clock   |
|-----------|------|--|--|
| To        |      |  |  |
| PLLACK    |      | –  | $3 \times \text{PLLACK} +$<br>$4 \times \text{SLCK} +$<br>$1.5 \times \text{PLLACK}$ |
| UPLLCKDIV |      | $3 \times \text{UPLLCKDIV} +$<br>$4 \times \text{SLCK} +$<br>$1.5 \times \text{UPLLCKDIV}$ | –  |

**Figure 31-9. Programmable Clock Output Programming**

### 31.19 Register Write Protection

To prevent any single software error from corrupting PMC behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the [PMC Write Protection Mode Register \(PMC\\_WPMR\)](#).

If a write access to a write-protected register is detected, the WPVS flag in the [PMC Write Protection Status Register \(PMC\\_WPSR\)](#) is set and the field WPVSR indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the PMC\_WPSR.

The following registers are write-protected when the WPEN bit is set in PMC\_WPMR:

- [PMC System Clock Disable Register](#)
- [PMC Peripheral Clock Enable Register 0](#)
- [PMC Peripheral Clock Disable Register 0](#)
- [PMC Clock Generator Main Oscillator Register](#)
- [PMC Clock Generator Main Clock Frequency Register](#)
- [PMC Clock Generator PLLA Register](#)
- [PMC UTMI Clock Configuration Register](#)
- [PMC Host Clock Register](#)
- [PMC USB Clock Register](#)
- [PMC Programmable Clock Register](#)
- [PMC Fast Startup Mode Register](#)
- [PMC Fast Startup Polarity Register](#)
- [PMC Peripheral Clock Enable Register1](#)
- [PMC Peripheral Clock Disable Register1](#)
- [PMC Oscillator Calibration Register](#)
- [PMC SleepWalking Enable Register 0](#)
- [PMC SleepWalking Disable Register 0](#)
- [PLL Maximum Multiplier Value Register](#)
- [PMC SleepWalking Enable Register 1](#)

- [PMC SleepWalking Disable Register 1](#)

### 31.20.1 PMC System Clock Enable Register

**Name:** PMC\_SCER  
**Offset:** 0x0000  
**Property:** Write-only

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

**Bits 8, 9, 10, 11, 12, 13, 14, 15 – PCK** Programmable Clock x Output Enable

| Value | Description  |
|-------|--|
| 0     | No effect.   |
| 1     | Enables the corresponding Programmable Clock output. |

**Bit 5 – USBCLK** Enable USB FS Clock

| Value | Description           |
|-------|-----------------------|
| 0     | No effect.            |
| 1     | Enables USB FS clock. |

### 31.20.2 PMC System Clock Disable Register

**Name:** PMC\_SCDR  
**Offset:** 0x0004  
**Property:** Write-only

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

| Reset  |     |                |     |     |     |    |    |    |        |  |

**Bits 23:20 – UPLLCOUNT[3:0]** UTMI PLL Startup Time  
 Specifies the number of SLCK cycles multiplied by 8 for the UTMI PLL startup time.

**Bit 16 – UPPLEN** UTMI PLL Enable  
 When UPPLEN is set, the LOCKU flag is set once the UTMI PLL startup time is achieved.

| Value | Description               |
|-------|---------------------------|
| 0     | The UTMI PLL is disabled. |
| 1     | The UTMI PLL is enabled.  |

### 31.20.8 PMC Clock Generator Main Oscillator Register

**Name:** CKGR\_MOR  
**Offset:** 0x0020  
**Reset:** 0x00000008  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

#### Bit 26 – XT32KFME 32.768 kHz Crystal Oscillator Frequency Monitoring Enable

| Value | Description   |
|-------|---|
| 0     | The 32.768 kHz crystal oscillator frequency monitoring is disabled. |
| 1     | The 32.768 kHz crystal oscillator frequency monitoring is enabled.  |

#### Bit 25 – CFDEN Clock Failure Detector Enable

| Value | Description                             |
|-------|---|
| 0     | The clock failure detector is disabled. |
| 1     | The clock failure detector is enabled.  |

#### Bit 24 – MOSCSEL Main Clock Oscillator Selection

| Value | Description                              |
|-------|--|
| 0     | The Main RC oscillator is selected.      |
| 1     | The Main crystal oscillator is selected. |

#### Bits 23:16 – KEY[7:0] Write Access Password

| Value | Name   | Description   |
|-------|--------|---|
| 0x37  | PASSWD | Writing any other value in this field aborts the write operation. |
|       |        | Always reads as 0.  |

#### Bits 15:8 – MOSCXTST[7:0] Main Crystal Oscillator Startup Time

Specifies the number of SLCK cycles multiplied by 8 for the main crystal oscillator startup time.

#### Bits 6:4 – MOSCRCF[2:0] Main RC Oscillator Frequency Selection

At startup, the Main RC oscillator frequency is 12 MHz.

| Value | Name  | Description                             |
|-------|-------|---|
| 0     | 4_MHz | The RC oscillator frequency is at 4 MHz |

# SAM E70/S70/V70/V71

## Power Management Controller (PMC)

| Value   | Name   | Description                              |
|---|--------|--|
| 1   | 8_MHz  | The RC oscillator frequency is at 8 MHz  |
| 2   | 12_MHz | The RC oscillator frequency is at 12 MHz |
| Note: MOSCRCF must be changed only if MOSCRCS is set in the PMC_SR. Therefore MOSCRCF and MOSRCEN cannot be changed at the same time. |        |  |

### Bit 3 – MOSRCEN Main RC Oscillator Enable

When MOSRCEN is set, the MOSCRCS flag is set once the Main RC oscillator startup time is achieved.

| Value | Description                         |
|-------|-------------------------------------|
| 0     | The Main RC oscillator is disabled. |
| 1     | The Main RC oscillator is enabled.  |

### Bit 2 – WAITMODE Wait Mode Command (write-only)

| Value | Description                   |
|-------|-------------------------------|
| 0     | No effect.                    |
| 1     | Puts the device in Wait mode. |

### Bit 1 – MOSCXTBY Main Crystal Oscillator Bypass

When MOSCXTBY is set, the MOSCXTS flag in PMC\_SR is automatically set. Clearing MOSCXTEN and MOSCXTBY bits clears the MOSCXTS flag.

| Value  | Description  |
|--|--|
| 0  | No effect.   |
| 1  | The Main crystal oscillator is bypassed. MOSCXTEN must be cleared. An external clock must be connected on XIN. |
| Note: When the crystal oscillator bypass is disabled (MOSCXTBY = 0), the MOSCXTS flag must be read at '0' in PMC_SR before enabling the crystal oscillator (MOSCXTEN = 1). |  |

### Bit 0 – MOSCXTEN Main Crystal Oscillator Enable

A crystal must be connected between XIN and XOUT.

When MOSCXTEN is set, the MOSCXTS flag is set once the Main crystal oscillator startup time is achieved.

| Value | Description   |
|-------|---|
| 0     | The Main crystal oscillator is disabled.                          |
| 1     | The Main crystal oscillator is enabled. MOSCXTBY must be cleared. |

### 31.20.9 PMC Clock Generator Main Clock Frequency Register

**Name:** CKGR\_MCFR  
**Offset:** 0x0024  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

|        |     |             |     |     |        |     |     |     |      |          |
|--------|-----|-------------|-----|-----|--------|-----|-----|-----|------|----------|
|        | Bit | 31          | 30  | 29  | 28     | 27  | 26  | 25  | 24   |          |
|        |     |             |     |     |        |     |     |     | CCSS |          |
| Access |     |             |     |     |        |     |     |     | R/W  |          |
| Reset  |     |             |     |     |        |     |     |     | 0    |          |
|        |     |             |     |     |        |     |     |     |      |          |
|        | Bit | 23          | 22  | 21  | 20     | 19  | 18  | 17  | 16   |          |
|        |     |             |     |     | RCMEAS |     |     |     |      | MAINFRDY |
| Access |     |             |     |     | R/W    |     |     |     |      | R/W      |
| Reset  |     |             |     |     | 0      |     |     |     |      | 0        |
|        |     |             |     |     |        |     |     |     |      |          |
|        | Bit | 15          | 14  | 13  | 12     | 11  | 10  | 9   | 8    |          |
|        |     | MAINF[15:8] |     |     |        |     |     |     |      |          |
| Access |     | R/W         | R/W | R/W | R/W    | R/W | R/W | R/W | R/W  |          |
| Reset  |     | 0           | 0   | 0   | 0      | 0   | 0   | 0   | 0    |          |
|        |     |             |     |     |        |     |     |     |      |          |
|        | Bit | 7           | 6   | 5   | 4      | 3   | 2   | 1   | 0    |          |
|        |     | MAINF[7:0]  |     |     |        |     |     |     |      |          |
| Access |     | R/W         | R/W | R/W | R/W    | R/W | R/W | R/W | R/W  |          |
| Reset  |     | 0           | 0   | 0   | 0      | 0   | 0   | 0   | 0    |          |

#### Bit 24 – CCSS Counter Clock Source Selection

| Value | Description   |
|-------|---|
| 0     | The measured clock of the MAINF counter is the Main RC oscillator.      |
| 1     | The measured clock of the MAINF counter is the Main crystal oscillator. |

#### Bit 20 – RCMEAS RC Oscillator Frequency Measure (write-only)

The measurement is performed on the main frequency (i.e., not limited to the Main RC oscillator only). If the source of MAINCK is the Main crystal oscillator, the restart of measurement may not be required because of the stability of crystal oscillators.

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Restarts measuring of the frequency of MAINCK. MAINF carries the new frequency as soon as a low-to-high transition occurs on the MAINFRDY flag. |

#### Bit 16 – MAINFRDY Main Clock Frequency Measure Ready

| Value | Description  |
|-------|--|
| 0     | MAINF value is not valid or the measured oscillator is disabled or a measure has just been started by means of RCMEAS. |
| 1     | The measured oscillator has been enabled previously and MAINF value is available.                                      |

Note: To ensure that a correct value is read on the MAINF field, the MAINFRDY flag must be read at '1' then another read access must be performed on the register to get a stable value on the MAINF field.

#### Bits 15:0 – MAINF[15:0] Main Clock Frequency

Gives the number of cycles of the clock selected by the bit CCSS within 16 SLCK periods. To calculate the frequency of the measured clock:

$$f_{SELCLK} = (\text{MAINF} \times f_{SLCK}) / 16$$

where frequency is in MHz.

### 31.20.10 PMC Clock Generator PLLA Register

**Name:** CKGR\_PLLAR  
**Offset:** 0x0028  
**Reset:** 0x00003F00  
**Property:** Read/Write

Possible limitations on PLLA input frequencies and multiplier factors should be checked before using the PMC.

Bit 29 must always be set to '1' when programming the CKGR\_PLLAR.

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

|        |           |     |                |     |     |            |     |     |
|--------|-----------|-----|----------------|-----|-----|------------|-----|-----|
| Bit    | 31        | 30  | 29             | 28  | 27  | 26         | 25  | 24  |

| Bit    | 7         | 6   | 5              | 4   | 3   | 2          | 1   | 0   |
|        | DIVA[7:0] |     |                |     |     |            |     |     |
| Access | R/W       | R/W | R/W            | R/W | R/W | R/W        | R/W | R/W |
| Reset  | 0         | 0   | 0              | 0   | 0   | 0          | 0   | 0   |

**Bit 29 – ONE** Must Be Set to 1

Bit 29 must always be set to '1' when programming the CKGR\_PLLAR.

**Bits 26:16 – MULA[10:0]** PLLA Multiplier

1 up to 62 = PLLCK frequency is the PLLA input frequency multiplied by MULA + 1.  
 Unlisted values are forbidden.

| Value | Description  |
|-------|--|
| 0     | The PLLA is disabled (PLLA also disabled if DIVA = 0). |

**Bits 13:8 – PLLACOUNT[5:0]** PLLA Counter

Specifies the number of SLCK cycles before the LOCKA bit is set in PMC\_SR after CKGR\_PLLAR is written.

**Bits 7:0 – DIVA[7:0]** PLLA Front End Divider

| Value | Name   | Description  |
|-------|--------|--|
| 0     | 0      | PLLA is disabled.                                      |
| 1     | BYPASS | Divider is bypassed (divide by 1) and PLLA is enabled. |
| 2–255 |        | Divider output is the selected clock divided by DIVA.  |

### 31.20.11 PMC Host Clock Register

**Name:** PMC\_MCKR  
**Offset:** 0x0030  
**Reset:** 0x00000001  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

|        |    |    |           |    |    |    |           |    |

| Access |    |    | UPLLDIV2  |    |    |    | MDIV[1:0] |    |
| Reset  |    |    | R/W       |    |    |    | R/W       |    |
| Reset  |    |    | 0         |    |    |    | 0         |    |
|        |    |    |           |    |    |    |           |    |
| Bit    | 7  | 6  | 5         | 4  | 3  | 2  | 1         | 0  |
| Access |    |    | PRES[2:0] |    |    |    | CSS[1:0]  |    |
| Reset  |    |    | R/W       |    |    |    | R/W       |    |
| Reset  |    |    | 0         |    |    |    | 0         |    |

#### Bit 13 – UPLLDIV2 UPLL Divider by 2

| Value | Description                       |
|-------|-----------------------------------|
| 0     | UPLLCK frequency is divided by 1. |
| 1     | UPLLCK frequency is divided by 2. |

#### Bits 9:8 – MDIV[1:0] Host Clock Division

| Value | Name     | Description               |
|-------|----------|---------------------------|
| 0     | EQ_PCK   | MCK is FCLK divided by 1. |
| 1     | PCK_DIV2 | MCK is FCLK divided by 2. |
| 2     | PCK_DIV4 | MCK is FCLK divided by 4. |
| 3     | PCK_DIV3 | MCK is FCLK divided by 3. |

#### Bits 6:4 – PRES[2:0] Processor Clock Prescaler

| Value | Name   | Description                  |
|-------|--------|------------------------------|
| 0     | CLK_1  | Selected clock               |
| 1     | CLK_2  | Selected clock divided by 2  |
| 2     | CLK_4  | Selected clock divided by 4  |
| 3     | CLK_8  | Selected clock divided by 8  |
| 4     | CLK_16 | Selected clock divided by 16 |
| 5     | CLK_32 | Selected clock divided by 32 |
| 6     | CLK_64 | Selected clock divided by 64 |
| 7     | CLK_3  | Selected clock divided by 3  |

#### Bits 1:0 – CSS[1:0] Host Clock Source Selection

| Value | Name     | Description        |
|-------|----------|--------------------|
| 0     | SLOW_CLK | SLCK is selected   |
| 1     | MAIN_CLK | MAINCK is selected |

# SAM E70/S70/V70/V71

## Power Management Controller (PMC)

| Value | Name     | Description            |
|-------|----------|------------------------|
| 2     | PLLA_CLK | PLLACK is selected     |
| 3     | UPLL_CLK | UPPLLCKDIV is selected |

### 31.20.12 PMC USB Clock Register

**Name:** PMC\_USB  
**Offset:** 0x0038  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

**Bits 11:8 – USBDIV[3:0]** Divider for USB\_48M  
 USB\_48M is input clock divided by USBDIV+1.

**Bit 0 – USBS** USB Input Clock Selection

| Value | Description            |
|-------|------------------------|
| 0     | USB_48M input is PLLA. |
| 1     | USB_48M input is UPLL. |

### 31.20.13 PMC Programmable Clock Register

**Name:** PMC\_PCKx [x=0..7]  
**Offset:** 0x0040  
**Reset:** 0  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

|        |           |     |     |     |           |          |     |     |
|--------|-----------|-----|-----|-----|-----------|----------|-----|-----|
| Bit    | 31        | 30  | 29  | 28  | 27        | 26       | 25  | 24  |
| Access |           |     |     |     |           |          |     |     |
| Reset  |           |     |     |     |           |          |     |     |

| Bit    | 7         | 6   | 5   | 4   | 3         | 2        | 1   | 0   |
| Access | PRES[3:0] |     |     |     |           | CSS[2:0] |     |     |
| Reset  | R/W       | R/W | R/W | R/W |           | R/W      | R/W | R/W |
|        | 0         | 0   | 0   | 0   |           | 0        | 0   | 0   |

#### Bits 11:4 – PRES[7:0] Programmable Clock Prescaler

| Value | Description                          |
|-------|--------------------------------------|
| 0-255 | Selected clock is divided by PRES+1. |

#### Bits 2:0 – CSS[2:0] Programmable Clock Source Selection

| Value | Name      | Description             |
|-------|-----------|-------------------------|
| 0     | SLOW_CLK  | SLCK is selected        |
| 1     | MAIN_CLK  | MAINCK is selected      |
| 2     | PLLA_CLK  | PLLACK is selected      |
| 3     | UPLL_CLK  | UPLLCKDIV is selected   |
| 4     | MCK       | MCK is selected         |
| 5     | AUDIO_CLK | AUDIOPLLCLK is selected |

### 31.20.14 PMC Interrupt Enable Register

**Name:** PMC\_IER  
**Offset:** 0x0060  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |         |         |          |         |         |         |         |          |
|--------|---------|---------|----------|---------|---------|---------|---------|----------|
| Bit    | 31      | 30      | 29       | 28      | 27      | 26      | 25      | 24       |
|        |         |         |          |         |         |         |         |          |
| Access |         |         |          |         |         |         |         |          |
| Reset  |         |         |          |         |         |         |         |          |
|        |         |         |          |         |         |         |         |          |
| Bit    | 23      | 22      | 21       | 20      | 19      | 18      | 17      | 16       |
|        |         |         | XT32KERR |         |         | CFDEV   | MOSCRCS | MOSCSELS |
| Access |         |         | W        |         |         | W       | W       | W        |

| Reset  |         |         |          |         |         |         |         |          |

**Bit 21 – XT32KERR** 32.768 kHz Crystal Oscillator Error Interrupt Enable

**Bit 18 – CFDEV** Clock Failure Detector Event Interrupt Enable

**Bit 17 – MOSCRCS** Main RC Oscillator Status Interrupt Enable

**Bit 16 – MOSCSELS** Main Clock Source Oscillator Selection Status Interrupt Enable

**Bits 8, 9, 10, 11, 12, 13, 14, 15 – PCKRDY** Programmable Clock Ready x Interrupt Enable

**Bit 6 – LOCKU** UTMI PLL Lock Interrupt Enable

**Bit 3 – MCKRDY** Host Clock Ready Interrupt Enable

**Bit 1 – LOCKA** PLLA Lock Interrupt Enable

**Bit 0 – MOSCXTS** Main Crystal Oscillator Status Interrupt Enable

### 31.20.15 PMC Interrupt Disable Register

**Name:** PMC\_IDR  
**Offset:** 0x0064  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |         |         |          |         |         |         |         |          |
|--------|---------|---------|----------|---------|---------|---------|---------|----------|
| Bit    | 31      | 30      | 29       | 28      | 27      | 26      | 25      | 24       |
|        |         |         |          |         |         |         |         |          |

#### Bit 21 – XT32KERR Slow Crystal Oscillator Error

| Value | Description  |
|-------|--|
| 0     | The frequency of the 32.768 kHz crystal oscillator is correct (32.768 kHz $\pm$ 1%) or the monitoring is disabled.   |
| 1     | The frequency of the 32.768 kHz crystal oscillator is incorrect or has been incorrect for an elapsed period of time since the monitoring has been enabled. |

#### Bit 20 – FOS Clock Failure Detector Fault Output Status

| Value | Description   |
|-------|---|
| 0     | The fault output of the clock failure detector is inactive.   |
| 1     | The fault output of the clock failure detector is active. This status is cleared by writing a '1' to FOCLR in PMC_FOCR. |

#### Bit 19 – CFDS Clock Failure Detector Status

| Value | Description   |
|-------|---|
| 0     | A clock failure of the Main crystal oscillator clock is not detected. |
| 1     | A clock failure of the Main crystal oscillator clock is detected.     |

#### Bit 18 – CFDEV Clock Failure Detector Event

| Value | Description   |
|-------|---|
| 0     | No clock failure detection of the Main crystal oscillator clock has occurred since the last read of PMC_SR.           |
| 1     | At least one clock failure detection of the Main crystal oscillator clock has occurred since the last read of PMC_SR. |

#### Bit 17 – MOSCRCS Main RC Oscillator Status

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Main RC oscillator is not stabilized. |
| 1     | Main RC oscillator is stabilized.     |

**Bit 16 – MOSCSELS** Main Clock Source Oscillator Selection Status

| Value | Description               |
|-------|---------------------------|
| 0     | Selection is in progress. |
| 1     | Selection is done.        |

**Bits 8, 9, 10, 11, 12, 13, 14, 15 – PCKRDY** Programmable Clock Ready Status

| Value | Description                        |
|-------|------------------------------------|
| 0     | Programmable Clock x is not ready. |
| 1     | Programmable Clock x is ready.     |

**Bit 7 – OSCSELS** Slow Clock Source Oscillator Selection

| Value | Description                                |
|-------|--|
| 0     | Slow RC oscillator is selected.            |
| 1     | 32.768 kHz crystal oscillator is selected. |

**Bit 6 – LOCKU** UTMI PLL Lock Status

| Value | Description            |
|-------|------------------------|
| 0     | UTMI PLL is not locked |
| 1     | UTMI PLL is locked.    |

**Bit 3 – MCKRDY** Host Clock Status

| Value | Description              |
|-------|--------------------------|
| 0     | Host Clock is not ready. |
| 1     | Host Clock is ready.     |

**Bit 1 – LOCKA** PLLA Lock Status

| Value | Description        |
|-------|--------------------|
| 0     | PLLA is not locked |
| 1     | PLLA is locked.    |

**Bit 0 – MOSCXTS** Main Crystal Oscillator Status

| Value | Description                                |
|-------|--|
| 0     | Main crystal oscillator is not stabilized. |
| 1     | Main crystal oscillator is stabilized.     |

### 31.20.17 PMC Interrupt Mask Register

**Name:** PMC\_IMR  
**Offset:** 0x006C  
**Reset:** 0x00000000  
**Property:** Read-only

The following configuration values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |         |         |          |         |         |         |         |          |       |         |
|--------|---------|---------|----------|---------|---------|---------|---------|----------|-------|---------|
| Bit    | 31      | 30      | 29       | 28      | 27      | 26      | 25      | 24       |       |         |
|        |         |         |          |         |         |         |         |          |       |         |
| Access |         |         |          |         |         |         |         |          |       |         |
| Reset  |         |         |          |         |         |         |         |          |       |         |

| Reset  | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

#### Bit 23 – FFLPM Force Flash Low-power Mode

| Value | Description  |
|-------|--|
| 0     | The Flash Low-power mode, defined in the FLPM field, is automatically applied when in Wait mode and released when going back to Active mode. |
| 1     | The Flash Low-power mode is user defined by the FLPM field and immediately applied.  |

#### Bits 22:21 – FLPM[1:0] Flash Low-power Mode

| Value | Name                 | Description  |
|-------|----------------------|--|
| 0     | FLASH_STANDBY        | Flash is in Standby Mode when system enters Wait Mode        |
| 1     | FLASH_DEEP_POWERDOWN | Flash is in Deep-powerdown mode when system enters Wait Mode |
| 2     | FLASH_IDLE           | Idle mode  |

#### Bit 20 – LPM Low-power Mode

| Value | Description   |
|-------|---|
| 0     | The WaitForInterrupt (WFI) or the WaitForEvent (WFE) instruction of the processor makes the processor enter Sleep mode. |
| 1     | The WaitForEvent (WFE) instruction of the processor makes the system enter Wait mode.                                   |

#### Bit 18 – USBAL USB Alarm Enable

| Value | Description   |
|-------|---|
| 0     | The USB alarm has no effect on the PMC.                 |
| 1     | The USB alarm enables a fast restart signal to the PMC. |

#### Bit 17 – RTCAL RTC Alarm Enable

| Value | Description   |
|-------|---|
| 0     | The RTC alarm has no effect on the PMC.                 |
| 1     | The RTC alarm enables a fast restart signal to the PMC. |

# SAM E70/S70/V70/V71

## Power Management Controller (PMC)

---

---

### Bit 16 – RTTAL RTT Alarm Enable

| Value | Description   |
|-------|---|
| 0     | The RTT alarm has no effect on the PMC.                 |
| 1     | The RTT alarm enables a fast restart signal to the PMC. |

### Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – FSTT Fast Startup Input Enable

| Value | Description   |
|-------|---|
| 0     | The corresponding wake-up input has no effect on the PMC.                 |
| 1     | The corresponding wake-up input enables a fast restart signal to the PMC. |

### 31.20.19 PMC Fast Startup Polarity Register

**Name:** PMC\_FSPR  
**Offset:** 0x0074  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

|        |        |        |        |        |        |        |       |       |

| Reset  | 0      | 0      | 0      | 0      | 0      | 0      | 0     | 0     |

**Bits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 – FSTP** Fast Startup Input Polarity x bits

Defines the active polarity of the corresponding wake-up input. If the corresponding wake-up input is enabled and at the FSTP level, it enables a fast restart signal.

**31.20.20 PMC Fault Output Clear Register**

**Name:** PMC\_FOCR  
**Offset:** 0x0078  
**Property:** Write-only

**Bit 0 – FOCLR** Fault Output Clear  
Clears the clock failure detector fault output.

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

| Value    | Name   | Description  |
|----------|--------|--|
| 0x504D43 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0. |

#### Bit 0 – WPEN Write Protection Enable

See ["Register Write Protection"](#) for the list of registers that can be write-protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x504D43 ("PMC" in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x504D43 ("PMC" in ASCII).  |

### 31.20.22 PMC Write Protection Status Register

**Name:** PMC\_WPSR  
**Offset:** 0x00E8

|        |     |                   |    |    |    |    |    |    |      |
|        | Bit | 7                 | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
|        |     | [Greyed out bits] |    |    |    |    |    |    | WPVS |
| Access |     |                   |    |    |    |    |    |    | R    |
| Reset  |     |                   |    |    |    |    |    |    | 0    |

**Bits 23:8 – WPVSR[15:0]** Write Protection Violation Source  
 When WPVS = 1, WPVSR indicates the register address offset at which a write access has been attempted.

**Bit 0 – WPVS** Write Protection Violation Status

| Value | Description   |
|-------|---|
| 0     | No write protection violation has occurred since the last read of the PMC_WPSR.   |
| 1     | A write protection violation has occurred since the last read of the PMC_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSR. |

# SAM E70/S70/V70/V71

## Power Management Controller (PMC)

### 31.20.23 PMC Peripheral Clock Enable Register 1

**Name:** PMC\_PCER1  
**Offset:** 0x0100  
**Property:** Write-only

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

|        |     |              |     | PID[6:0] |     |              |              |     |     |
| Access |     |              | R/W | R/W      | R/W | R/W          | R/W          | R/W | R/W |
| Reset  |     |              | 0   | 0        | 0   | 0            | 0            | 0   | 0   |

#### Bit 29 – GCLKEN Generic Clock Enable

| Value | Description                             |
|-------|---|
| 0     | The selected generic clock is disabled. |
| 1     | The selected generic clock is enabled.  |

#### Bit 28 – EN Enable

| Value | Description                            |
|-------|--|
| 0     | Selected Peripheral clock is disabled. |
| 1     | Selected Peripheral clock is enabled.  |

#### Bits 27:20 – GCLKDIV[7:0] Generic Clock Division Ratio

Generic clock is the selected clock period divided by GCLKDIV + 1.  
 GCLKDIV must not be changed while the peripheral selects GCLKx (e.g., bit rate, etc.).

#### Bit 12 – CMD Command

| Value | Description |
|-------|-------------|
| 0     | Read mode.  |
| 1     | Write mode. |

#### Bits 10:8 – GCLKCSS[2:0] Generic Clock Source Selection

| Value | Name      | Description             |
|-------|-----------|-------------------------|
| 0     | SLOW_CLK  | SLCK is selected        |
| 1     | MAIN_CLK  | MAINCK is selected      |
| 2     | PLLA_CLK  | PLLACK is selected      |
| 3     | UPLL_CLK  | UPLLCK is selected      |
| 4     | MCK_CLK   | MCK is selected         |
| 5     | AUDIO_CLK | AUDIOPLLCLK is selected |

**Bits 6:0 – PID[6:0] Peripheral ID**

Peripheral ID selection from PID2 to PID127.

“PID2 to PID127” refers to identifiers as defined in section “Peripheral Identifiers”.

### 31.20.27 PMC Oscillator Calibration Register

**Name:** PMC\_OCR  
**Offset:** 0x0110  
**Reset:** 0x00404040  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

#### Bit 23 – SEL12 Selection of Main RC Oscillator Calibration Bits for 12 MHz

| Value | Description  |
|-------|--|
| 0     | Factory-determined value stored in Flash memory.       |
| 1     | Value written by user in CAL12 field of this register. |

#### Bits 22:16 – CAL12[6:0] Main RC Oscillator Calibration Bits for 12 MHz Calibration bits applied to the RC Oscillator when SEL12 is set.

#### Bit 15 – SEL8 Selection of Main RC Oscillator Calibration Bits for 8 MHz

| Value | Description   |
|-------|---|
| 0     | Factory-determined value stored in Flash memory.      |
| 1     | Value written by user in CAL8 field of this register. |

#### Bits 14:8 – CAL8[6:0] Main RC Oscillator Calibration Bits for 8 MHz Calibration bits applied to the RC Oscillator when SEL8 is set.

#### Bit 7 – SEL4 Selection of Main RC Oscillator Calibration Bits for 4 MHz

| Value | Description   |
|-------|---|
| 0     | Default value stored in Flash memory.                 |
| 1     | Value written by user in CAL4 field of this register. |

#### Bits 6:0 – CAL4[6:0] Main RC Oscillator Calibration Bits for 4 MHz Calibration bits applied to the RC Oscillator when SEL4 is set.

### 31.20.28 PMC SleepWalking Enable Register 0

**Name:** PMC\_SLPWK\_ER0  
**Offset:** 0x0114  
**Property:** Write-only

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

| Reset  |     |       |       |       |       |       |       |       |       |

**Bits 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 – PIDx** Peripheral x SleepWalking Enable

Not all PIDs can be configured with asynchronous partial wake-up.

Only the following PID can be configured with asynchronous partial wake-up: UARTx and TWIHSx.

The clock of the peripheral must be enabled before using its asynchronous partial wake-up (SleepWalking) function (its associated PIDx field in [PMC Peripheral Clock Status Register 0](#) or [PMC Peripheral Clock Status Register 1](#) is set to '1').

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | The asynchronous partial wakeup (SleepWalking) function of the corresponding peripheral is enabled.<br><br><b>Note:</b> "PIDx" refers to identifiers as defined in the section "Peripheral Identifiers" |

# SAM E70/S70/V70/V71

## Power Management Controller (PMC)

### 31.20.29 PMC SleepWalking Enable Register 1

**Name:** PMC\_SLPWK\_ER1  
**Offset:** 0x0134  
**Property:** Write-only

This register can only be written if the WPEN bit is cleared in the [PMC Write Protection Mode Register](#).

Not all PIDs can be configured with asynchronous partial wake-up.

Only the following PIDs can be configured with asynchronous partial wake-up: UARTx and TWIHSx.

| Value | Description  |
|-------|--|
| 0     | The asynchronous partial wake-up (SleepWalking) function of the peripheral is currently disabled or the peripheral enabled for asynchronous partial wake-up (SleepWalking) cleared the PIDn bit upon detection of a wake-up condition. |
| 1     | The asynchronous partial wake-up (SleepWalking) function of the peripheral is currently enabled.   |
|       | <b>Note:</b> "PIDx" refers to identifiers as defined in the section "Peripheral Identifiers".  |

**Bits 10:0 – PLLA\_MMAX[10:0]** PLLA Maximum Allowed Multiplier Value

Defines the maximum value of multiplication factor that can be sent to PLLA. Any value of the MULA field (see [PMC Clock Generator PLLA Register](#)) above PLLA\_MMAX is saturated to PLLA\_MMAX. PLLA\_MMAX write operation is cancelled in the following cases:

- The value of MULA is currently saturated by PLLA\_MMAX
- The user is trying to write a value of PLLA\_MMAX that is smaller than the current value of MULA

#### Bits 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21 – PIDx Peripheral Activity x Status

| Value   | Description   |
|---|---|
| 0   | The peripheral x is not currently active. The asynchronous partial wake-up (SleepWalking) function can be activated.  |
| 1   | The peripheral x is currently active. The asynchronous partial wake-up (SleepWalking) function must not be activated. |
| <b>Note:</b> “PIDx” refers to identifiers as defined in the section “Peripheral Identifiers”. |   |

#### Bit 5 – PIDx Peripheral Activity x Status

# SAM E70/S70/V70/V71

## Power Management Controller (PMC)

| Value | Description  |
|-------|--|
| 0     | The peripheral x is not currently active. The asynchronous partial wake-up (SleepWalking) function can be activated.   |
| 1     | The peripheral x is currently active. The asynchronous partial wake-up (SleepWalking) function must not be activated.<br><b>Note:</b> "PIDx" refers to identifiers as defined in the section "Peripheral Identifiers". |

### Bits 0, 1, 2, 3 – PIDx Peripheral Activity x Status

| Value | Description  |
|-------|--|
| 0     | The peripheral x is not currently active. The asynchronous partial wake-up (SleepWalking) function can be activated.   |
| 1     | The peripheral x is currently active. The asynchronous partial wake-up (SleepWalking) function must not be activated.<br><b>Note:</b> "PIDx" refers to identifiers as defined in the section "Peripheral Identifiers". |

**31.20.37 PMC SleepWalking Activity In Progress Register**

**Name:** PMC\_SLPWK\_AIPR  
**Offset:** 0x0144  
**Property:** Read-only

**Bit 0 – AIP** Activity In Progress

Only the following PIDs can be configured with asynchronous partial wakeup: UARTx and TWIHSx.

| Value | Description  |
|-------|--|
| 0     | There is no activity on peripherals. The asynchronous partial wakeup (SleepWalking) function can be activated on one or more peripherals. The device can enter Wait mode.        |
| 1     | One or more peripherals are currently active. The device must not enter Wait mode if the asynchronous partial wakeup is enabled for one of the following PIDs: UARTx and TWIHSx. |

## 32. Parallel Input/Output Controller (PIO)

### 32.1 Description

The Parallel Input/Output Controller (PIO) manages up to fully programmable input/output lines. Each I/O line may be dedicated as a general-purpose I/O or be assigned to a function of an embedded peripheral. This ensures effective optimization of the pins of the product.

Each I/O line is associated with a bit number in all of the 32-bit registers of the 32-bit wide user interface.

Each I/O line of the PIO Controller features the following:

- An input change interrupt enabling level change detection on any I/O line
- Additional Interrupt modes enabling rising edge, falling edge, low-level or high-level detection on any I/O line
- A glitch filter providing rejection of glitches lower than one-half of peripheral clock cycle
- A debouncing filter providing rejection of unwanted pulses from key or push button operations
- Multi-drive capability similar to an open drain I/O line
- Control of the I/O line pullup and pulldown
- Input visibility and output control

The PIO Controller also features a synchronous output providing up to bits of data output in a single write operation.

An 8-bit Parallel Capture mode is also available which can be used to interface a CMOS digital image sensor, an ADC, a DSP synchronous port in Synchronous mode, etc.

### 32.2 Embedded Characteristics

- Up to Programmable I/O Lines
- Fully Programmable through Set/Clear Registers
- Multiplexing of Four Peripheral Functions per I/O Line
- For each I/O Line (Whether Assigned to a Peripheral or Used as General Purpose I/O)
  - Input Change Interrupt
  - Programmable Glitch Filter
  - Programmable Debouncing Filter
  - Multi-drive Option Enables Driving in Open Drain
  - Programmable Pullup on Each I/O Line
  - Pin Data Status Register, Supplies Visibility of the Level on the Pin at Any Time
  - Additional Interrupt Modes on a Programmable Event: Rising Edge, Falling Edge, Low-Level or High-Level
  - Lock of the Configuration by the Connected Peripheral
- Synchronous Output, Provides Set and Clear of Several I/O Lines in a Single Write
- Register Write Protection
- Programmable Schmitt Trigger Inputs
- Programmable I/O Drive
- Parallel Capture Mode
  - Can Be Used to Interface a CMOS Digital Image Sensor, an ADC, etc.
  - One Clock, 8-bit Parallel Data and Two Data Enable on I/O Lines
  - Data Can be Sampled Every Other Time (For Chrominance Sampling Only)
  - Supports Connection of One DMA Controller Channel Which Offers Buffer Reception Without Processor Intervention

### 32.3 Block Diagram

Figure 32-1. Block Diagram

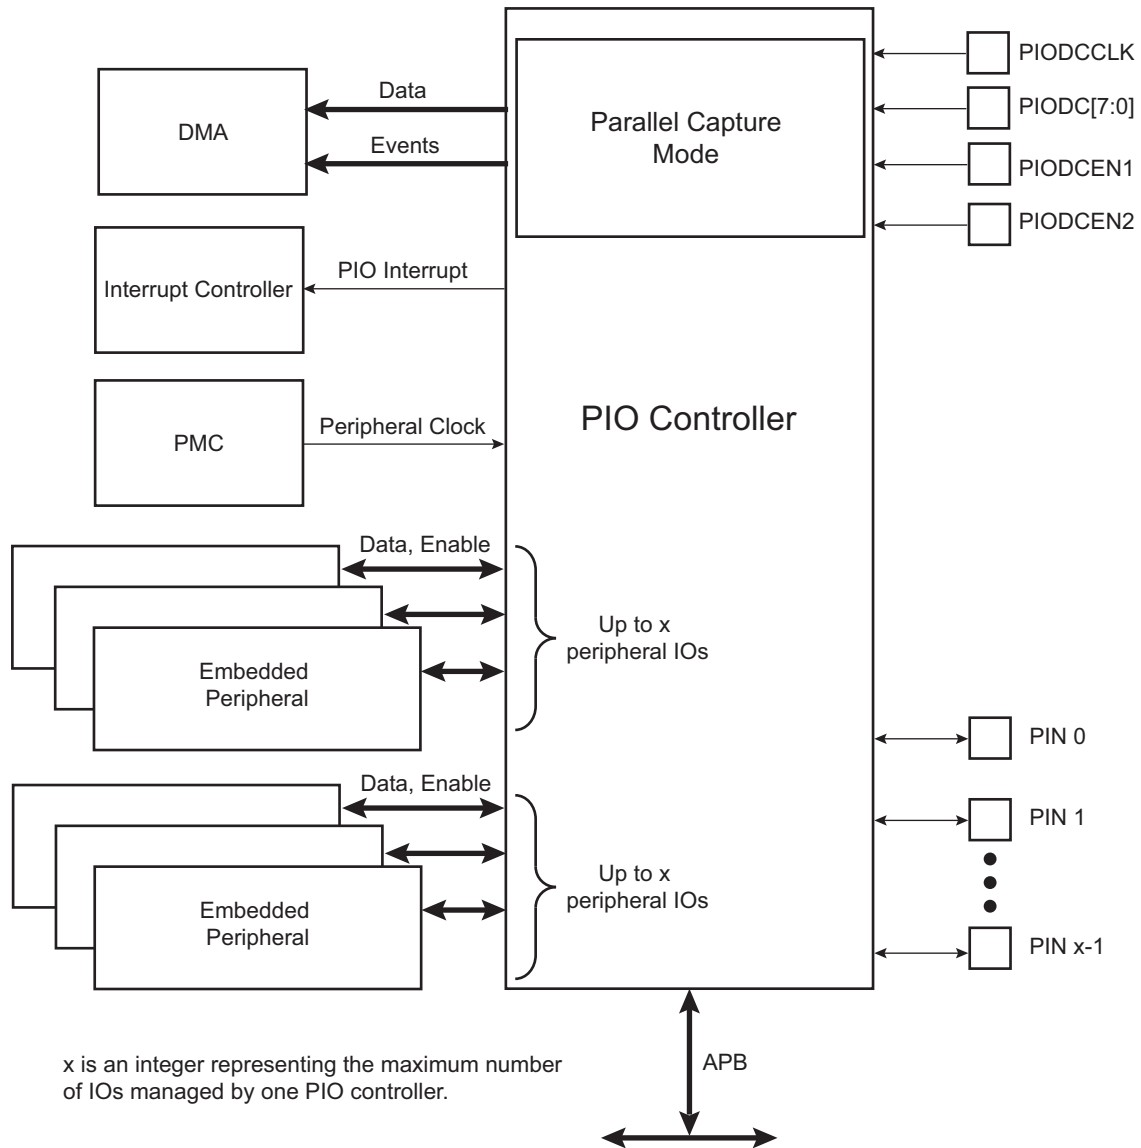

Table 32-1. Signal Description

| Signal Name | Signal Description                  | Signal Type |
|-------------|-------------------------------------|-------------|
| PIODCCLK    | Parallel Capture Mode Clock         | Input       |
| PIODC[7:0]  | Parallel Capture Mode Data          | Input       |
| PIODCEN1    | Parallel Capture Mode Data Enable 1 | Input       |
| PIODCEN2    | Parallel Capture Mode Data Enable 2 | Input       |

## **32.4 Product Dependencies**

### **32.4.1 Pin Multiplexing**

Each pin is configurable, depending on the product, as either a general-purpose I/O line only, or as an I/O line multiplexed with one or two peripheral I/Os. As the multiplexing is hardware defined and thus product-dependent, the hardware designer and programmer must carefully determine the configuration of the PIO Controllers required by their application. When an I/O line is general-purpose only, i.e., not multiplexed with any peripheral I/O, programming of the PIO Controller regarding the assignment to a peripheral has no effect and only the PIO Controller can control how the pin is driven by the product.

### **32.4.2 External Interrupt Lines**

When the WKUPx input pins must be used as external interrupt lines, the PIO Controller must be configured to disable the peripheral control on these IOs, and the corresponding IO lines must be set to Input mode.

### **32.4.3 Power Management**

The Power Management Controller controls the peripheral clock in order to save power. Writing any of the registers of the user interface does not require the peripheral clock to be enabled. This means that the configuration of the I/O lines does not require the peripheral clock to be enabled.

However, when the clock is disabled, not all of the features of the PIO Controller are available, including glitch filtering. Note that the input change interrupt, the interrupt modes on a programmable event and the read of the pin level require the clock to be validated.

After a hardware reset, the peripheral clock is disabled by default.

The user must configure the Power Management Controller before any access to the input line information.

### **32.4.4 Interrupt Sources**

For interrupt handling, the PIO Controllers are considered as user peripherals. This means that the PIO Controller interrupt lines are connected among the interrupt sources. Refer to the PIO Controller peripheral identifier in the Peripheral Identifiers table to identify the interrupt sources dedicated to the PIO Controllers. Using the PIO Controller requires the Interrupt Controller to be programmed first.

The PIO Controller interrupt can be generated only if the peripheral clock is enabled.

## **32.5 Functional Description**

The PIO Controller features up to fully-programmable I/O lines. Most of the control logic associated to each I/O is represented in the following figure. In this description each signal shown represents one of up to possible indexes.

**Figure 32-2. Port n I/O Line Control Logic**

### 32.5.1 Pullup and Pulldown Resistor Control

Each I/O line is designed with an embedded pullup resistor and an embedded pulldown resistor. The pullup resistor can be enabled or disabled by writing to the Pull-Up Enable Register (PIO\_PUER) or Pull-Up Disable Register (PIO\_PUDR), respectively. Writing to these registers results in setting or clearing the corresponding bit in the Pull-Up Status Register (PIO\_PUSR). Reading a one in PIO\_PUSR means the pullup is disabled and reading a zero means the pullup is enabled. The pulldown resistor can be enabled or disabled by writing the Pull-Down Enable Register (PIO\_PPDER) or the Pull-Down Disable Register (PIO\_PPDDR), respectively. Writing in these registers results in setting or clearing the corresponding bit in the Pull-Down Status Register (PIO\_PPDSR). Reading a one in PIO\_PPDSR means the pullup is disabled and reading a zero means the pulldown is enabled.

Enabling the pulldown resistor while the pullup resistor is still enabled is not possible. In this case, the write of PIO\_PPDER for the relevant I/O line is discarded. Likewise, enabling the pullup resistor while the pulldown resistor is still enabled is not possible. In this case, the write of PIO\_PUER for the relevant I/O line is discarded.

Control of the pullup resistor is possible regardless of the configuration of the I/O line.

After reset, depending on the I/O, pullup or pulldown can be set.

### 32.5.2 I/O Line or Peripheral Function Selection

When a pin is multiplexed with one or two peripheral functions, the selection is controlled with the Enable Register (PIO\_PER) and the Disable Register (PIO\_PDR). The Status Register (PIO\_PSR) is the result of the set and clear registers and indicates whether the pin is controlled by the corresponding peripheral or by the PIO Controller. A value of zero indicates that the pin is controlled by the corresponding on-chip peripheral selected in the Peripheral ABCD Select registers (PIO\_ABCDSR0 and PIO\_ABCDSR1). A value of one indicates the pin is controlled by the PIO Controller.

If a pin is used as a general-purpose I/O line (not multiplexed with an on-chip peripheral), the PIO\_PER and PIO\_PDR have no effect and the PIO\_PSR returns a one for the corresponding bit.

After reset, the I/O lines are controlled by the PIO Controller, that is, the PIO\_PSR resets at one. However, in some events, it is important that PIO lines are controlled by the peripheral (as in the case of memory chip select lines that must be driven inactive after reset, or for address lines that must be driven low for booting out of an external memory). Thus, the reset value of the PIO\_PSR is defined at the product level and depends on the multiplexing of the device.

### 32.5.3 Peripheral A or B or C or D Selection

The PIO Controller provides multiplexing of up to four peripheral functions on a single pin. The selection is performed by writing the PIO\_ABCDSR0 and PIO\_ABCDSR1.

For each pin:

- The corresponding bit at level zero in the PIO\_ABCDSR0 and the corresponding bit at level zero in the PIO\_ABCDSR1 means peripheral A is selected.
- The corresponding bit at level one in the PIO\_ABCDSR0 and the corresponding bit at level zero in the PIO\_ABCDSR1 means peripheral B is selected.
- The corresponding bit at level zero in the PIO\_ABCDSR0 and the corresponding bit at level one in the PIO\_ABCDSR1 means peripheral C is selected.
- The corresponding bit at level one in the PIO\_ABCDSR0 and the corresponding bit at level one in the PIO\_ABCDSR1 means peripheral D is selected.

Multiplexing of peripheral lines A, B, C and D only affects the output line. The peripheral input lines are always connected to the pin input, for additional information, refer to Figure 32-2. "Port n I/O Line Control Logic".

Writing in the PIO\_ABCDSR0 and PIO\_ABCDSR1 manages the multiplexing regardless of the configuration of the pin. However, assignment of a pin to a peripheral function requires a write in the PIO\_ABCDSR0 and PIO\_ABCDSR1 in addition to a write in the PIO\_PDR.

After reset, the PIO\_ABCDSR0 and PIO\_ABCDSR1 are zero, thus indicating that all the PIO lines are configured on peripheral A. However, peripheral A generally does not drive the pin as the PIO Controller resets in I/O Line mode.

If the software selects a peripheral A, B, C or D which does not exist for a pin, no alternate functions are enabled for this pin and the selection is taken into account. The PIO Controller does not carry out checks to prevent selection of a peripheral which does not exist.

### 32.5.4 Output Control

When the I/O line is assigned to a peripheral function, that is, the corresponding bit in the PIO\_PSR is at zero, the drive of the I/O line is controlled by the peripheral. Peripheral A or B, or C or D depending on the value in the PIO\_ABCDSR0 and PIO\_ABCDSR1 determines whether the pin is driven or not.

When the I/O line is controlled by the PIO Controller, the pin can be configured to be driven. This is done by writing the Output Enable Register (PIO\_OER) and Output Disable Register (PIO\_ODR). The results of these write operations are detected in the Output Status Register (PIO\_OSR). When a bit in this register is at zero, the corresponding I/O line is used as an input only. When the bit is at one, the corresponding I/O line is driven by the PIO Controller.

The level driven on an I/O line can be determined by writing in the Set Output Data Register (PIO\_SODR) and the Clear Output Data Register (PIO\_CODR). These write operations, respectively, set and clear the Output Data Status Register (PIO\_ODSR), which represents the data driven on the I/O lines. Writing in the PIO\_OER and PIO\_ODR manages the PIO\_OSR whether the pin is configured to be controlled by the PIO Controller or assigned to a peripheral function. This enables configuration of the I/O line prior to setting it to be managed by the PIO Controller.

Similarly, writing in the PIO\_SODR and PIO\_CODR affects the PIO\_ODSR. This is important as it defines the first level driven on the I/O line.

### 32.5.5 Synchronous Data Output

Clearing one or more PIO line(s) and setting another one or more PIO line(s) synchronously cannot be done by using PIO\_SODR and PIO\_CODR. It requires two successive write operations into two different registers. To overcome this, the PIO Controller offers a direct control of PIO outputs by single write access to PIO\_ODSR. Only bits unmasked by the Output Write Status Register (PIO\_OWSR) are written. The mask bits in PIO\_OWSR are set by writing to the Output Write Enable Register (PIO\_OWER) and cleared by writing to the Output Write Disable Register (PIO\_OWDR).

After reset, the synchronous data output is disabled on all the I/O lines as PIO\_OWSR resets at 0x0.

### 32.5.6 Multi-Drive Control (Open Drain)

Each I/O can be independently programmed in open drain by using the multi-drive feature. This feature permits several drivers to be connected on the I/O line which is driven low only by each device. An external pullup resistor (or enabling of the internal one) is generally required to guarantee a high level on the line.

The multi-drive feature is controlled by the Multi-driver Enable Register (PIO\_MDER) and the Multi-driver Disable Register (PIO\_MDDR). The multi-drive can be selected whether the I/O line is controlled by the PIO Controller or assigned to a peripheral function. The Multi-driver Status Register (PIO\_MDSR) indicates the pins that are configured to support external drivers.

After reset, the multi-drive feature is disabled on all pins, i.e., PIO\_MDSR resets at value 0x0.

### 32.5.7 Output Line Timings

The following figure shows how the outputs are driven either by writing PIO\_SODR or PIO\_CODR, or by directly writing PIO\_ODSR. This last case is valid only if the corresponding bit in PIO\_OWSR is set. The Output Line Timings figure also shows when the feedback in the Pin Data Status Register (PIO\_PDSR) is available.

**Figure 32-3. Output Line Timings**

### 32.5.8 Inputs

The level on each I/O line can be read through PIO\_PDSR. This register indicates the level of the I/O lines regardless of their configuration, whether uniquely as an input, or driven by the PIO Controller, or driven by a peripheral.

Reading the I/O line levels requires the clock of the PIO Controller to be enabled, otherwise PIO\_PDSR reads the levels present on the I/O line at the time the clock was disabled.

### 32.5.9 Input Glitch and Debouncing Filters

Optional input glitch and debouncing filters are independently programmable on each I/O line.

The glitch filter can filter a glitch with a duration of less than 1/2 peripheral clock and the debouncing filter can filter a pulse of less than 1/2 period of a programmable divided slow clock.

# SAM E70/S70/V70/V71

## Parallel Input/Output Controller (PIO)

The selection between glitch filtering or debounce filtering is done by writing in the PIO Input Filter Slow Clock Disable Register (PIO\_IFSCDR) and the PIO Input Filter Slow Clock Enable Register (PIO\_IFSCER). Writing PIO\_IFSCDR and PIO\_IFSCER, respectively, sets and clears bits in the Input Filter Slow Clock Status Register (PIO\_IFSCSR).

The current selection status can be checked by reading the PIO\_IFSCSR.

- If PIO\_IFSCSR[i] = 0: The glitch filter can filter a glitch with a duration of less than 1/2 Host clock period.
- If PIO\_IFSCSR[i] = 1: The debouncing filter can filter a pulse with a duration of less than 1/2 programmable divided slow clock period.

For the debouncing filter, the period of the divided slow clock is defined by writing in the DIV field of the Slow Clock Divider Debouncing Register (PIO\_SCDR):

$$t_{div\_sclk} = ((DIV + 1) \times 2) \times t_{sclk}$$

When the glitch or debouncing filter is enabled, a glitch or pulse with a duration of less than 1/2 selected clock cycle (selected clock represents peripheral clock or divided slow clock depending on PIO\_IFSCDR and PIO\_IFSCER programming) is automatically rejected, while a pulse with a duration of one selected clock (peripheral clock or divided slow clock) cycle or more is accepted. For pulse durations between 1/2 selected clock cycle and one selected clock cycle, the pulse may or may not be taken into account, depending on the precise timing of its occurrence. Thus for a pulse to be visible, it must exceed one selected clock cycle, whereas for a glitch to be reliably filtered out, its duration must not exceed 1/2 selected clock cycle.

The filters also introduce some latencies, illustrated in the following two figures.

The glitch filters are controlled by the Input Filter Enable Register (PIO\_IFER), the Input Filter Disable Register (PIO\_IFDR) and the Input Filter Status Register (PIO\_IFSR). Writing PIO\_IFER and PIO\_IFDR respectively sets and clears bits in PIO\_IFSR. This last register enables the glitch filter on the I/O lines.

When the glitch and/or debouncing filter is enabled, it does not modify the behavior of the inputs on the peripherals. It acts only on the value read in PIO\_PDSR and on the input change interrupt detection. The glitch and debouncing filters require that the peripheral clock is enabled.

**Figure 32-4. Input Glitch Filter Timing**

**Figure 32-5. Input Debouncing Filter Timing**

### 32.5.10 Input Edge/Level Interrupt

The PIO Controller can be programmed to generate an interrupt when it detects an edge or a level on an I/O line. The Input Edge/Level interrupt is controlled by writing the Interrupt Enable Register (PIO\_IER) and the Interrupt Disable Register (PIO\_IDR), which enable and disable the input change interrupt respectively by setting and clearing the corresponding bit in the Interrupt Mask Register (PIO\_IMR). As input change detection is possible only by comparing two successive samplings of the input of the I/O line, the peripheral clock must be enabled. The Input Change interrupt is available regardless of the configuration of the I/O line, i.e., configured as an input only, controlled by the PIO Controller or assigned to a peripheral function.

By default, the interrupt can be generated at any time an edge is detected on the input.

Some additional interrupt modes can be enabled/disabled by writing in the Additional Interrupt Modes Enable Register (PIO\_AIMER) and Additional Interrupt Modes Disable Register (PIO\_AIMDR). The current state of this selection can be read through the Additional Interrupt Modes Mask Register (PIO\_AIMMR).

These additional modes are:

- Rising edge detection
- Falling edge detection
- Low-level detection
- High-level detection

In order to select an additional interrupt mode:

- The type of event detection (edge or level) must be selected by writing in the Edge Select Register (PIO\_ESR) and Level Select Register (PIO\_LSR) which select, respectively, the edge and level detection. The current status of this selection is accessible through the Edge/Level Status Register (PIO\_ELSR).
- The polarity of the event detection (rising/falling edge or high/low-level) must be selected by writing in the Falling Edge/Low-Level Select Register (PIO\_FELLSR) and Rising Edge/High-Level Select Register (PIO\_REHLSR) which allow to select falling or rising edge (if edge is selected in PIO\_ELSR) edge or high- or low-level detection (if level is selected in PIO\_ELSR). The current status of this selection is accessible through the Fall/Rise - Low/High Status Register (PIO\_FRLHSR).

When an input edge or level is detected on an I/O line, the corresponding bit in the Interrupt Status Register (PIO\_ISR) is set. If the corresponding bit in PIO\_IMR is set, the PIO Controller interrupt line is asserted. The interrupt signals of the channels are ORed-wired together to generate a single interrupt signal to the interrupt controller.

When the software reads PIO\_ISR, all the interrupts are automatically cleared. This signifies that all the interrupts that are pending when PIO\_ISR is read must be handled. When an Interrupt is enabled on a “level”, the interrupt is generated as long as the interrupt source is not cleared, even if some read accesses in PIO\_ISR are performed.

**Figure 32-6. Event Detector on Input Lines (Figure Represents Line 0)**

Example of interrupt generation on following lines:

- Rising edge on PIO line 0
- Falling edge on PIO line 1
- Rising edge on PIO line 2
- Low-level on PIO line 3
- High-level on PIO line 4
- High-level on PIO line 5
- Falling edge on PIO line 6
- Rising edge on PIO line 7
- Any edge on the other lines

The following table provides the required configuration for this example.

**Table 32-2. Configuration for Example Interrupt Generation**

| Configuration                                   | Description   |
|---|---|
| Interrupt Mode                                  | All the interrupt sources are enabled by writing 32'hFFFF_FFFF in PIO_IER. Then the additional Interrupt mode is enabled for lines 0 to 7 by writing 32'h0000_00FF in PIO_AIMER.  |
| Edge or Level Detection                         | Lines 3, 4 and 5 are configured in level detection by writing 32'h0000_0038 in PIO_LSR. The other lines are configured in edge detection by default, if they have not been previously configured. Otherwise, lines 0, 1, 2, 6 and 7 must be configured in edge detection by writing 32'h0000_00C7 in PIO_ESR.   |
| Falling/Rising Edge or Low/High-Level Detection | Lines 0, 2, 4, 5 and 7 are configured in rising edge or high-level detection by writing 32'h0000_00B5 in PIO_REHLSR. The other lines are configured in falling edge or low-level detection by default if they have not been previously configured. Otherwise, lines 1, 3 and 6 must be configured in falling edge/low-level detection by writing 32'h0000_004A in PIO_FELLSR. |

**Figure 32-7. Input Change Interrupt Timings When No Additional Interrupt Modes**

### 32.5.11 I/O Lines Lock

When an I/O line is controlled by a peripheral (particularly the Pulse-Width Modulation (PWM) Controller), it can become locked by the action of this peripheral through an input of the PIO Controller. When an I/O line is locked, the write of the corresponding bit in the PIO\_PER, PIO\_PDR, PIO\_MDER, PIO\_MDDR, PIO\_PUDR, PIO\_PUER, PIO\_ABCDSR0 and PIO\_ABCDSR1 is discarded to lock its configuration. The user can know at any time which I/O line is locked by reading the PIO Lock Status Register (PIO\_LOCKSR). Once an I/O line is locked, the only way to unlock it is to apply a hardware reset to the PIO Controller.

### 32.5.12 Programmable I/O Drive

It is possible to configure the I/O drive for pads. Refer to the section “Electrical Characteristics”.

### 32.5.13 Programmable Schmitt Trigger

It is possible to configure each input for the Schmitt trigger. By default the Schmitt trigger is active. Disabling the Schmitt trigger is requested when using the QTouch® Library.

### 32.5.14 Parallel Capture Mode

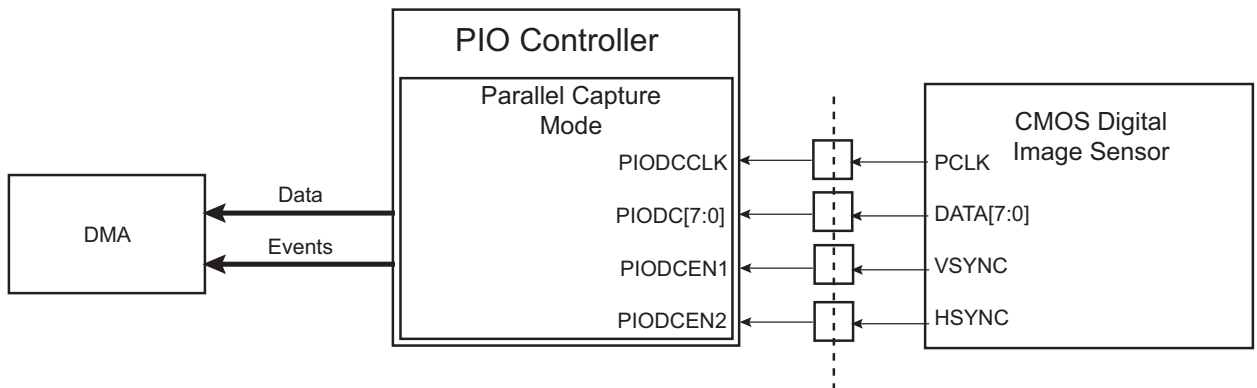

#### 32.5.14.1 Overview

The PIO Controller integrates an interface able to read data from a CMOS digital image sensor, a high-speed parallel ADC, a DSP synchronous port in Synchronous mode, etc. For better understanding and to ease reading, the following description uses an example with a CMOS digital image sensor.

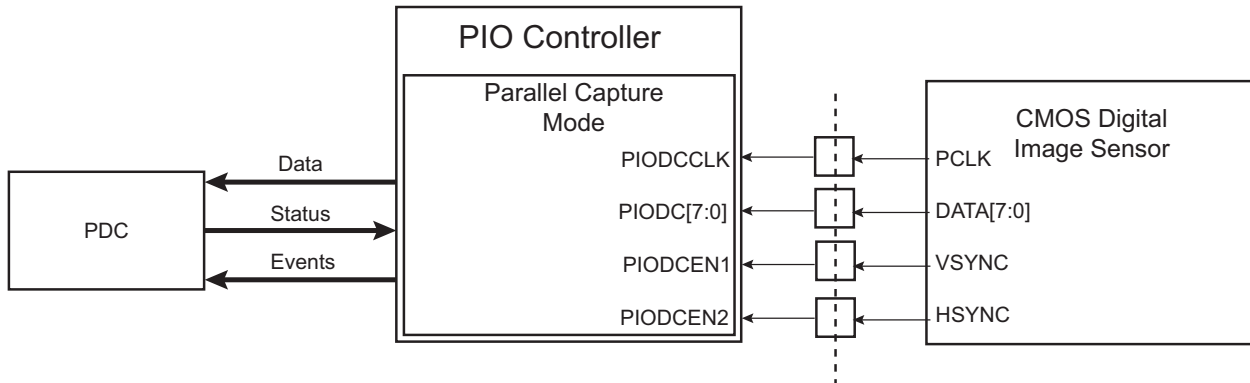

#### 32.5.14.2 Functional Description

The CMOS digital image sensor provides a sensor clock, an 8-bit data synchronous with the sensor clock and two data enables which are also synchronous with the sensor clock.

**Figure 32-8. PIO Controller Connection with CMOS Digital Image Sensor**

**Figure 32-9. PIO Controller Connection with CMOS Digital Image Sensor**

As soon as the Parallel Capture mode is enabled by writing a one to the PCEN bit in PIO\_PCMR, the I/O lines connected to the sensor clock (PIODCCCLK), the sensor data (PIODC[7:0]) and the sensor data enable signals (PIODCEN1 and PIODCEN2) are configured automatically as inputs. To know which I/O lines are associated with the sensor clock, the sensor data and the sensor data enable signals, refer to the I/O multiplexing table(s) in the section “Package and Pinout”.

Once enabled, the Parallel Capture mode samples the data at rising edge of the sensor clock and resynchronizes it with the peripheral clock domain.

The size of the data which can be read in PIO\_PCRHR can be programmed using the DSIZE field in PIO\_PCMR. If this data size is larger than 8 bits, then the Parallel Capture mode samples several sensor data to form a concatenated data of size defined by DSIZE. Then this data is stored in PIO\_PCRHR and the flag DRDY is set to one in PIO\_PCISR.

The Parallel Capture mode can be associated with a reception channel of the DMA Controller. This performs reception transfer from Parallel Capture mode to a memory buffer without any intervention from the CPU.

The Parallel Capture mode can be associated with a reception channel of the Peripheral DMA Controller (PDC). This performs reception transfer from Parallel Capture mode to a memory buffer without any intervention from the CPU. Transfer status signals from PDC are available in PIO\_PCISR through the flags ENDRX and RXBUFF.

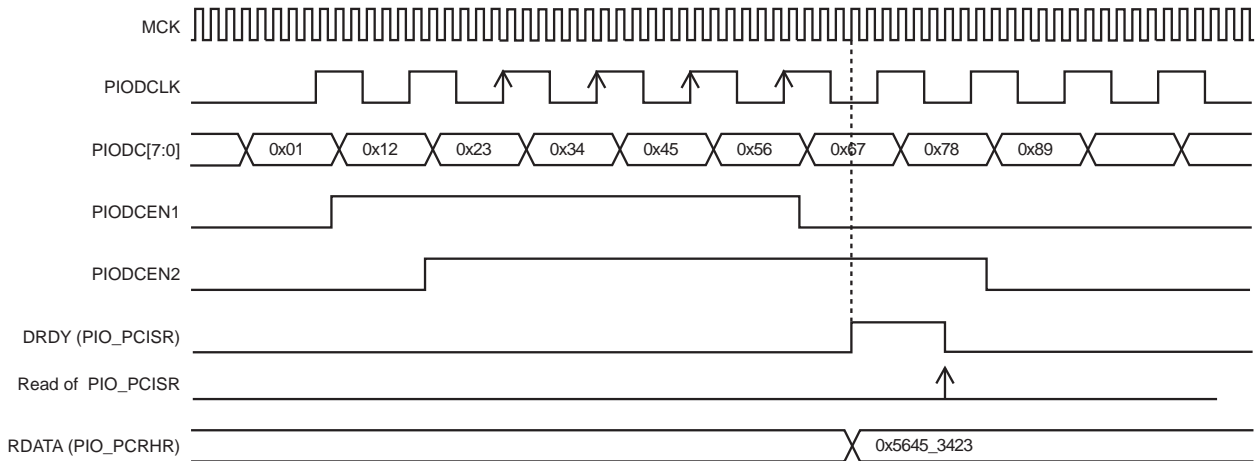

The Parallel Capture mode can take into account the sensor data enable signals or not. If the bit ALWYS is set to zero in PIO\_PCMR, the Parallel Capture mode samples the sensor data at the rising edge of the sensor clock only if both data enable signals are active (at one). If the bit ALWYS is set to one, the Parallel Capture mode samples the sensor data at the rising edge of the sensor clock whichever the data enable signals are.

The Parallel Capture mode can sample the sensor data only one time out of two. This is particularly useful when the user wants only to sample the luminance Y of a CMOS digital image sensor which outputs a YUV422 data stream. If the HALFS bit is set to zero in PIO\_PCMR, the Parallel Capture mode samples the sensor data in the conditions described above. If the HALFS bit is set to one in PIO\_PCMR, the Parallel Capture mode samples the sensor data in the conditions described above, but only one time out of two. Depending on the FRSTS bit in PIO\_PCMR, the sensor can either sample the even or odd sensor data. If sensor data are numbered in the order that they are received with an index from zero to n, if FRSTS equals zero then only data with an even index are sampled. If FRSTS equals one, then only data with an odd index are sampled. If data is ready in PIO\_PCRHR and it is not read before a new data is stored in PIO\_PCRHR, then an overrun error occurs. The previous data is lost and the OVRE flag in PIO\_PCISR is set to one. This flag is automatically reset when PIO\_PCISR is read (reset after read).

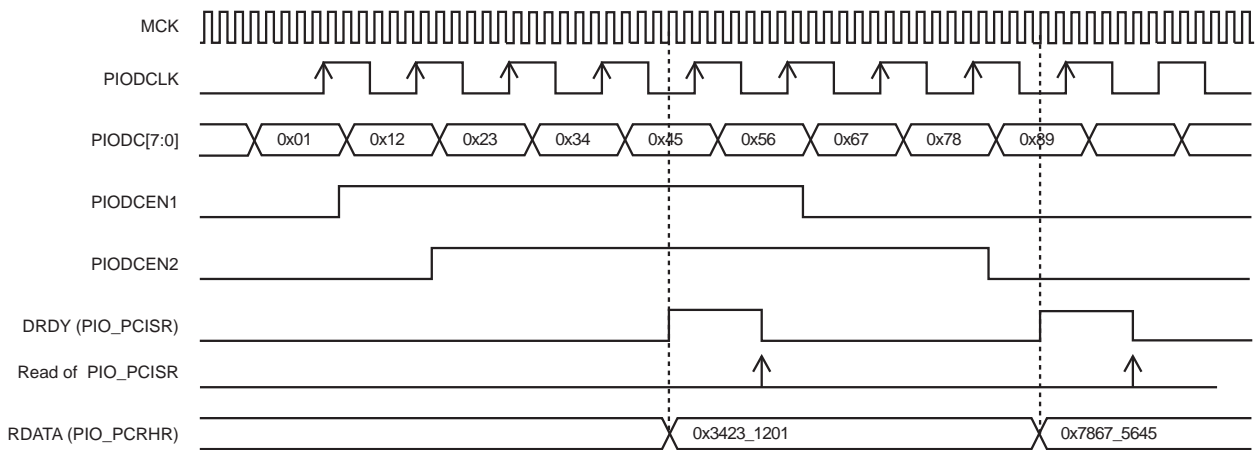

The flags DRDY and OVRE can be a source of the PIO interrupt.

The flags DRDY, OVRE, ENDRX and RXBUFF can be a source of the PIO interrupt.

**Figure 32-10. Parallel Capture Mode Waveforms (DSIZE = 2, ALWAYS = 0, HALFS = 0)**

**Figure 32-11. Parallel Capture Mode Waveforms (DSIZE = 2, ALWAYS = 1, HALFS = 0)**

**Figure 32-12. Parallel Capture Mode Waveforms (DSIZE = 2, ALWAYS = 0, HALFS = 1, FRSTS = 0)**

**Figure 32-13. Parallel Capture Mode Waveforms (DSIZE = 2, ALWAYS = 0, HALFS = 1, FRSTS = 1)**

### 32.5.14.3 Restrictions

- Configuration fields DSIZE, ALWAYS, HALFS and FRSTS in PIO\_PCMR can be changed ONLY if the Parallel Capture mode is disabled at this time (PCEN = 0 in PIO\_PCMR).
- The frequency of peripheral clock must be strictly superior to two times the frequency of the clock of the device which generates the parallel data.

### 32.5.14.4 Programming Sequence

#### 32.5.14.4.1 Without DMA

1. Write PIO\_PCIDR and PIO\_PCIER in order to configure the Parallel Capture mode interrupt mask.
2. Write PIO\_PCMR to set the fields DSIZE, ALWAYS, HALFS and FRSTS in order to configure the Parallel Capture mode WITHOUT enabling the Parallel Capture mode.
3. Write PIO\_PCMR to set the PCEN bit to one in order to enable the Parallel Capture mode WITHOUT changing the previous configuration.
4. Wait for a data ready by polling the DRDY flag in PIO\_PCISR or by waiting for the corresponding interrupt.
5. Check OVRE flag in PIO\_PCISR.
6. Read the data in PIO\_PCRHR.
7. If new data are expected, go to step 4.
8. Write PIO\_PCMR to set the PCEN bit to zero in order to disable the Parallel Capture mode WITHOUT changing the previous configuration.

#### 32.5.14.4.2 With DMA

1. Write PIO\_PCIDR and PIO\_PCIER in order to configure the Parallel Capture mode interrupt mask.
2. Configure DMA transfer in DMA registers.
3. Write PIO\_PCMR to set the fields DSIZE, ALWAYS, HALFS and FRSTS in order to configure the Parallel Capture mode WITHOUT enabling the Parallel Capture mode.
4. Write PIO\_PCMR to set PCEN bit to one in order to enable the Parallel Capture mode WITHOUT changing the previous configuration.
5. Wait for the DMA status flag to indicate that the buffer transfer is complete.
6. Check OVRE flag in PIO\_PCISR.
7. If a new buffer transfer is expected, go to step 5.
8. Write PIO\_PCMR to set the PCEN bit to zero in order to disable the Parallel Capture mode WITHOUT changing the previous configuration.

### 32.5.15 I/O Lines Programming Example

The programming example shown in the following table is used to obtain the following configuration:

- 4-bit output port on I/O lines 0 to 3 (should be written in a single write operation), open-drain, with pullup resistor

# SAM E70/S70/V70/V71

## Parallel Input/Output Controller (PIO)

- Four output signals on I/O lines 4 to 7 (to drive LEDs for example), driven high and low, no pullup resistor, no pulldown resistor
- Four input signals on I/O lines 8 to 11 (to read push-button states for example), with pullup resistors, glitch filters and input change interrupts
- Four input signals on I/O line 12 to 15 to read an external device status (polled, thus no input change interrupt), no pullup resistor, no glitch filter
- I/O lines 16 to 19 assigned to peripheral A functions with pullup resistor
- I/O lines 20 to 23 assigned to peripheral B functions with pulldown resistor
- I/O lines 24 to 27 assigned to peripheral C with input change interrupt, no pullup resistor and no pulldown resistor
- I/O lines 28 to 31 assigned to peripheral D, no pullup resistor and no pulldown resistor

**Table 32-3. Programming Example**

| Register    | Value to be Written |
|-------------|---------------------|
| PIO_PER     | 0x0000_FFFF         |
| PIO_PDR     | 0xFFFF_0000         |
| PIO_OER     | 0x0000_00FF         |
| PIO_ODR     | 0xFFFF_FF00         |
| PIO_IFER    | 0x0000_0F00         |
| PIO_IFDR    | 0xFFFF_F0FF         |
| PIO_SODR    | 0x0000_0000         |
| PIO_CODR    | 0x0FFF_FFFF         |
| PIO_IER     | 0x0F00_0F00         |
| PIO_IDR     | 0xF0FF_F0FF         |
| PIO_MDER    | 0x0000_000F         |
| PIO_MDDR    | 0xFFFF_FFF0         |
| PIO_PUDR    | 0xFFF0_00F0         |
| PIO_PUER    | 0x000F_FF0F         |
| PIO_PPDDR   | 0xFF0F_FFFF         |
| PIO_PPDER   | 0x00F0_0000         |
| PIO_ABCDSR0 | 0xF0F0_0000         |
| PIO_ABCDSR1 | 0xFF00_0000         |
| PIO_OWER    | 0x0000_000F         |
| PIO_OWDR    | 0x0FFF_FFF0         |

### 32.5.16 Register Write Protection

To prevent any single software error from corrupting PIO behavior, certain registers in the address space can be write-protected by setting the WPEN bit in the [PIO Write Protection Mode Register \(PIO\\_WPMR\)](#).

If a write access to a write-protected register is detected, the WPVS flag in the [PIO Write Protection Status Register \(PIO\\_WPSR\)](#) is set and the field WPVSRC indicates the register in which the write access has been attempted.

The WPVS bit is automatically cleared after reading the [PIO\\_WPSR](#).

The following registers can be write-protected:

- [PIO Enable Register](#)

# SAM E70/S70/V70/V71

## Parallel Input/Output Controller (PIO)

### 32.6 Register Summary

Each I/O line controlled by the PIO Controller is associated with a bit in each of the PIO Controller User Interface registers. Each register is 32 bits wide. If a parallel I/O line is not defined, writing to the corresponding bits has no effect. Undefined bits read zero. If the I/O line is not multiplexed with any peripheral, the I/O line is controlled by the PIO Controller and PIO\_PSR returns one systematically.

| Offset              | Name     | Bit Pos. | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

| Value    | Name   | Description   |
|----------|--------|---|
| 0x50494F | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit.<br>Always reads as 0. |

#### Bit 0 – WPEN Write Protection Enable

Refer to [“Register Write Protection”](#) for the list of registers that can be protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x50494F (“PIO” in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x50494F (“PIO” in ASCII).  |

|        |     |              |    |    |    |    |    |    |      |
|        | Bit | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8    |
|        |     | WPVSR[7:0]   |    |    |    |    |    |    |      |
| Access |     | R            | R  | R  | R  | R  | R  | R  | R    |
| Reset  |     | 0            | 0  | 0  | 0  | 0  | 0  | 0  | 0    |
|        |     |              |    |    |    |    |    |    |      |
|        | Bit | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
|        |     | [Greyed out] |    |    |    |    |    |    | WPVS |
| Access |     |              |    |    |    |    |    |    | R    |
| Reset  |     |              |    |    |    |    |    |    | 0    |

**Bits 23:8 – WPVSR[15:0]** Write Protection Violation Source  
 When WPVS = 1, WPVSR indicates the register address offset at which a write access has been attempted.

**Bit 0 – WPVS** Write Protection Violation Status

| Value | Description   |
|-------|---|
| 0     | No write protection violation has occurred since the last read of the PIO_WPSR.   |
| 1     | A write protection violation has occurred since the last read of the PIO_WPSR. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSR. |

| Value | Name       | Description   |
|-------|------------|---------------|
| 0     | LOW_DRIVE  | Lowest drive  |
| 1     | HIGH_DRIVE | Highest drive |

### 32.6.50 PIO Parallel Capture Mode Register

**Name:** PIO\_PCMR  
**Offset:** 0x0150  
**Reset:** 0x00000000  
**Property:** Read/Write

This register can only be written if the WPEN bit is cleared in the [PIO Write Protection Mode Register](#).

#### Bit 11 – FRSTS Parallel Capture Mode First Sample

This bit is useful only if the HALFS bit is set to 1. If data are numbered in the order that they are received with an index from 0 to n:

| Value | Description                               |
|-------|---|
| 0     | Only data with an even index are sampled. |
| 1     | Only data with an odd index are sampled.  |

#### Bit 10 – HALFS Parallel Capture Mode Half Sampling

Independently from the ALWYS bit:

| Value | Description   |
|-------|---|
| 0     | The Parallel Capture mode samples all the data.                   |
| 1     | The Parallel Capture mode samples the data only every other time. |

#### Bit 9 – ALWYS Parallel Capture Mode Always Sampling

| Value | Description   |
|-------|---|
| 0     | The Parallel Capture mode samples the data when both data enables are active. |
| 1     | The Parallel Capture mode samples the data whatever the data enables are.     |

#### Bits 5:4 – DSIZE[1:0] Parallel Capture Mode Data Size

| Value | Name      | Description   |
|-------|-----------|---|
| 0     | BYTE      | The reception data in the PIO_PCRHR is a byte (8-bit)       |
| 1     | HALF-WORD | The reception data in the PIO_PCRHR is a half-word (16-bit) |
| 2     | WORD      | The reception data in the PIO_PCRHR is a word (32-bit)      |
| 3     | Reserved  | Reserved  |

#### Bit 0 – PCEN Parallel Capture Mode Enable

| Value | Description                            |
|-------|--|
| 0     | The Parallel Capture mode is disabled. |

# SAM E70/S70/V70/V71

## Parallel Input/Output Controller (PIO)

| Value | Description                           |
|-------|---------------------------------------|
| 1     | The Parallel Capture mode is enabled. |

### 32.6.51 PIO Parallel Capture Interrupt Enable Register

**Name:** PIO\_PCIER  
**Offset:** 0x0154  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Enables the corresponding interrupt

**Bit 3 – RXBUFF** Reception Buffer Full Interrupt Enable

**Bit 2 – ENDRX** End of Reception Transfer Interrupt Enable

**Bit 1 – OVRE** Parallel Capture Mode Overrun Error Interrupt Enable

**Bit 0 – DRDY** Parallel Capture Mode Data Ready Interrupt Enable

### 32.6.52 PIO Parallel Capture Interrupt Disable Register

**Name:** PIO\_PCIDR  
**Offset:** 0x0158  
**Property:** Write-only

The following configuration values are valid for all listed bit names of this register:

0: No effect

1: Disables the corresponding interrupt

- Bit 3 – RXBUFF** Reception Buffer Full Interrupt Disable
- Bit 2 – ENDRX** End of Reception Transfer Interrupt Disable
- Bit 1 – OVRE** Parallel Capture Mode Overrun Error Interrupt Disable
- Bit 0 – DRDY** Parallel Capture Mode Data Ready Interrupt Disable

### 32.6.53 PIO Parallel Capture Interrupt Mask Register

**Name:** PIO\_PCIMR  
**Offset:** 0x015C  
**Reset:** 0x00000000  
**Property:** Read-only

The following configuration values are valid for all listed bit names of this register:

0: Corresponding interrupt is not enabled.

1: Corresponding interrupt is enabled.

|        |    |    |    |    |        |       |      |      |

|        |     | [Register Bit Field] |    |                      |    |        |       |      |      |
| Access |     |                      |    |                      |    |        |       |      |      |
| Reset  |     |                      |    |                      |    |        |       |      |      |
|        |     |                      |    |                      |    |        |       |      |      |
|        | Bit | 7                    | 6  | 5                    | 4  | 3      | 2     | 1    | 0    |
|        |     | [Register Bit Field] |    | [Register Bit Field] |    | RXBUFF | ENDRX | OVRE | DRDY |
| Access |     |                      |    |                      |    | R      | R     | R    | R    |
| Reset  |     |                      |    |                      |    | 0      | 0     | 0    | 0    |

**Bit 3 – RXBUFF** Reception Buffer Full

| Value | Description  |
|-------|--|
| 0     | The signal Buffer Full from the reception PDC channel is inactive. |
| 1     | The signal Buffer Full from the reception PDC channel is active.   |

**Bit 2 – ENDRX** End of Reception Transfer

| Value | Description  |
|-------|--|
| 0     | The End of Transfer signal from the reception PDC channel is inactive. |
| 1     | The End of Transfer signal from the reception PDC channel is active.   |

**Bit 1 – OVRE** Parallel Capture Mode Overrun Error

The OVRE flag is automatically reset when this register is read or when the Parallel Capture mode is disabled.

| Value | Description   |
|-------|---|
| 0     | No overrun error occurred since the last read of this register.           |
| 1     | At least one overrun error occurred since the last read of this register. |

**Bit 0 – DRDY** Parallel Capture Mode Data Ready

The DRDY flag is automatically reset when PIO\_PCRHR is read or when the Parallel Capture mode is disabled.

| Value | Description   |
|-------|---|
| 0     | No new data is ready to be read since the last read of PIO_PCRHR. |
| 1     | A new data is ready to be read since the last read of PIO_PCRHR.  |

**Bits 31:0 – RDATA[31:0]** Parallel Capture Mode Reception Data  
 If DSIZE = 0 in PIO\_PCMR, only the 8 LSBs of RDATA are useful.  
 If DSIZE = 1 in PIO\_PCMR, only the 16 LSBs of RDATA are useful.

## **33. External Bus Interface**

### **33.1 Description**

The External Bus Interface (EBI) is designed to ensure the successful data transfer between several external devices and the embedded Memory Controller of an Arm-based device.

The Static Memory is an external Memory Controller on the EBI. This external Memory Controller is capable of handling several types of external memory and peripheral devices, such as SRAM, PROM, EPROM, EEPROM, and Flash. The EBI operates with a 1.8V or 3.3V power supply.

**Note:** The SAMV7x devices operates at 3.3V only.

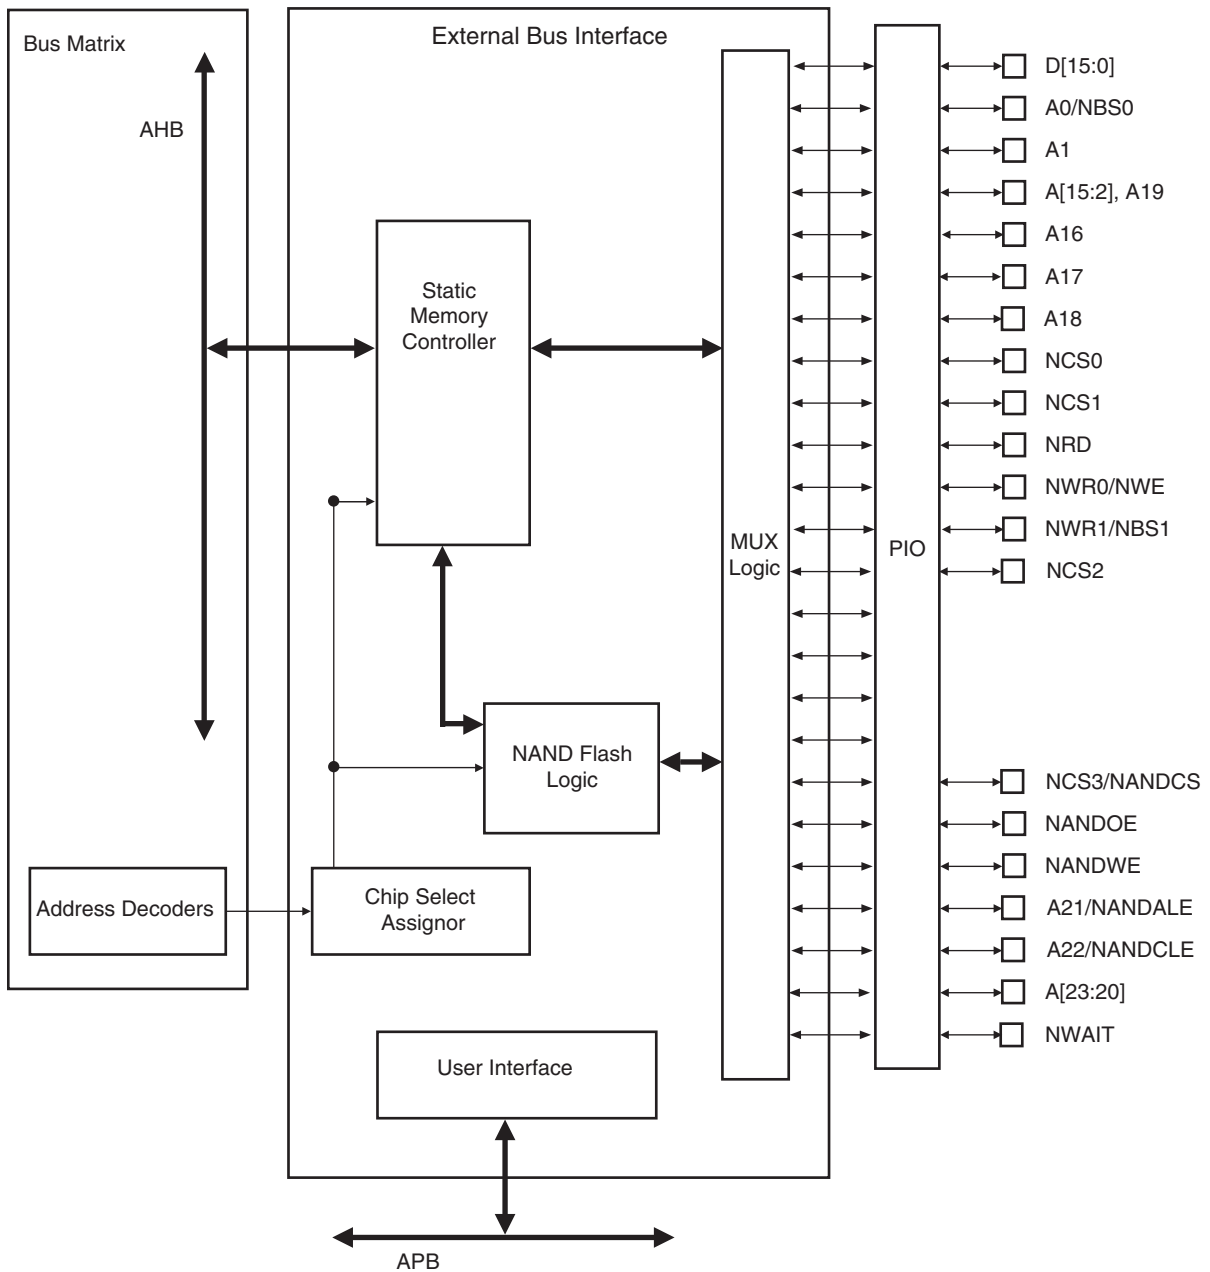

The EBI also supports the NAND Flash protocols through integrated circuitry that reduces the requirements for external components. Additionally, the EBI handles data transfers with up to six external devices, each assigned to six address spaces defined by the embedded Memory Controller. Data transfers are performed through a 16-bit or 32-bit data bus, an address bus of up to 24 bits, up to four chip select lines (NCS[3:0]) and several control pins that are generally multiplexed between the different external Memory Controllers.

### **33.2 Embedded Characteristics**

- Integrates one External Memory Controller
  - Static Memory Controller
- Integrates NAND Flash Logic
- Up to 24-bit Address Bus (up to 16 Mbytes linear per chip select)
- Up to four Chip Selects, Configurable Assignment
  - Static Memory Controller on NCS0, NCS1, NCS2, NCS3
  - NAND Flash support on NCS0, NCS1, NSCS2 and NCS3

### 33.3 EBI Block Diagram

Figure 33-1. Organization of the External Bus Interface

### 33.4 I/O Lines Description

Table 33-1. EBI I/O Lines Description

| Name   | Function | Type | Active Level |
|--------|----------|------|--------------|
| EBI    |          |      |              |
| D0–D15 | Data Bus | I/O  |              |

| .....continued             |                             |        |              |
|----------------------------|-----------------------------|--------|--------------|
| Name                       | Function                    | Type   | Active Level |
| A0–A23                     | Address Bus                 | Output |              |
| NWAIT                      | External Wait Signal        | Input  | Low          |
| SMC                        |                             |        |              |
| NCS0–EBI_NCS3              | Chip Select Lines           | Output | Low          |
| NWR0–NWR1                  | Write Signals               | Output | Low          |
| NRD                        | Read Signal                 | Output | Low          |
| NWE                        | Write Enable                | Output | Low          |
| NBS0–NBS1                  | Byte Mask Signals           | Output | Low          |
| EBI for NAND Flash Support |                             |        |              |
| NANDCS                     | NAND Flash Chip Select Line | Output | Low          |
| NANDOE                     | NAND Flash Output Enable    | Output | Low          |
| NANDWE                     | NAND Flash Write Enable     | Output | Low          |

The connection of some signals through the MUX logic is not direct and depends on the Memory Controller in use at the moment.

The following table details the connections between the SMC Memory Controller and the EBI pins.

**Table 33-2. EBI Pins and Memory Controllers I/O Lines Connections**

| EBIx Pins | SMC I/O Lines |
|-----------|---------------|
| NWR1/NBS1 | NWR1          |
| A0/NBS0   | SMC_A0        |
| A1        | SMC_A1        |
| A[11:2]   | SMC_A[11:2]   |
| A12       | SMC_A12       |
| A[15:13]  | SMC_A[15:13]  |
| A[25:16]  | SMC_A[25:16]  |
| D[15:0]   | D[15:0]       |

## 33.5 Application Example

### 33.5.1 Hardware Interface

The following table details the connections to be applied between the EBI pins and the external devices for each Memory Controller.

**Table 33-3. EBI Pins and External Static Device Connections**

| Signals:<br>EBI_ | Pins of the Interfaced Device |                             |                         |
|------------------|-------------------------------|-----------------------------|-------------------------|
|                  | 8-bit<br>Static Device        | 2 x 8-bit<br>Static Devices | 16-bit<br>Static Device |
| Controller       | SMC                           |                             |                         |
| D0–D7            | D0–D7                         | D0–D7                       | D0–D7                   |
| D8–D15           | –                             | D8–D15                      | D8–D15                  |
| A0/NBS0          | A0                            | –                           | NLB                     |
| A1               | A1                            | A0                          | A0                      |
| A2–A23           | A[2:23]                       | A[1:22]                     | A[1:22]                 |
| NCS0             | CS                            | CS                          | CS                      |
| NCS1             | CS                            | CS                          | CS                      |
| NCS2             | CS                            | CS                          | CS                      |
| NCS3/NANDCS      | CS                            | CS                          | CS                      |
| NRD              | OE                            | OE                          | OE                      |
| NWR0/NWE         | WE                            | WE (see <b>Note</b> )       | WE                      |
| NWR1/NBS1        | –                             | WE (see <b>Note</b> )       | NUB                     |

**Note:** NWR1 enables upper byte writes. NWR0 enables lower byte writes.

**Table 33-4. EBI Pins and External Device Connections**

| Signals:<br>EBI_ | Power supply | Pins of the Interfaced Device |
|------------------|--------------|-------------------------------|
|                  |              | NAND Flash                    |

### 33.5.2 Product Dependencies

#### 33.5.2.1 I/O Lines

The pins used for interfacing the External Bus Interface may be multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the External Bus Interface pins to their peripheral function. If I/O lines of the External Bus Interface are not used by the application, they can be used for other purposes by the PIO Controller.

### 33.5.3 Functional Description

The EBI transfers data between the internal AHB Bus (handled by the Bus Matrix) and the external memories or peripheral devices. It controls the waveforms and the parameters of the external address, data and control buses and is composed of the following elements:

- Static Memory Controller (SMC)
- A chip select assignment feature that assigns an AHB address space to the external devices
- A multiplex controller circuit that shares the pins between the different Memory Controllers
- Programmable NAND Flash support logic

#### 33.5.3.1 Bus Multiplexing

The EBI offers a complete set of control signals that share the 16-bit data lines, the address lines of up to 24 bits and the control signals through a multiplex logic operating in function of the memory area requests.

Multiplexing is specifically organized in order to guarantee the maintenance of the address and output control lines at a stable state while no external access is being performed. Multiplexing is also designed to respect the data float times defined in the Memory Controllers.

#### 33.5.3.2 Static Memory Controller

For information on the Static Memory Controller, refer to [34. Static Memory Controller \(SMC\)](#)

#### 33.5.3.3 NAND Flash Support

External Bus Interfaces integrate circuitry that interfaces to NAND Flash devices.

To ensure that the processor preserves transaction order and thus the correct NAND Flash behavior, the NAND Flash address space is to be declared in the Memory Protection Unit (MPU) as “Device” or “Strongly-ordered” memory. Refer to the ARM Cortex-M7 Technical Reference Manual (ARM DDI 0489) available on [www.arm.com](http://www.arm.com).

### External Bus Interface

The NAND Flash Chip Select (NANDCS) is driven by the Static Memory Controller on the NCS0, NCS1, NCS2 or NCS3 address space depending on value of SMC\_SMCSx bits. For example, programming the SMC\_NFC3 field in the CCFG\_SMCNFC3 Register in the Chip Configuration User Interface to the appropriate value enables the NAND Flash logic. For details on this register, refer to [19. Bus Matrix \(MATRIX\)](#). Access to an external NAND Flash device is then made by accessing the address space reserved to NCS3 (i.e., between 0x6300 0000 and 0x6FFF FFFF).

The NAND Flash logic drives the read and write command signals of the SMC on the NANDOE and NANDWE signals when the required SMC\_NFC3 signal is active. NANDOE and NANDWE are invalidated as soon as the transfer address fails to lie in the selected NCSx address space. For details on these waveforms, refer to [34. Static Memory Controller \(SMC\)](#).

### NAND Flash Signals

The address latch enable and command latch enable signals on the NAND Flash device are driven by address bits A22 and A21 of the EBI address bus. The command, address or data words on the data bus of the NAND Flash device are distinguished by using their address within the NCSx address space. The chip enable (CE) signal of the device and the ready/busy (R/B) signals are connected to PIO lines. The CE signal then remains asserted even when NCSx is not selected, preventing the device from returning to standby mode.

## 34. Static Memory Controller (SMC)

### 34.1 Description

The External Bus Interface (EBI) is designed to ensure the successful data transfer between several external devices and the ARM-based microcontroller. The Static Memory Controller (SMC) is part of the EBI.

The SMC handles several types of external memory and peripheral devices, such as SRAM, PSRAM, PROM, EPROM, EEPROM, LCD Module, NOR Flash and NAND Flash.

The SMC generates the signals that control the access to the external memory devices or peripheral devices. It has 4 chip selects, a 24-bit address bus, and a configurable 8 or 16-bit data bus. Separate read and write control signals allow for direct memory and peripheral interfacing. Read and write signal waveforms are fully adjustable.

The SMC can manage wait requests from external devices to extend the current access. The SMC is provided with an automatic Slow clock mode. In Slow clock mode, it switches from user-programmed waveforms to slow-rate specific waveforms on read and write signals. The SMC supports asynchronous burst read in Page mode access for page sizes up to 32 bytes.

The external data bus can be scrambled/unscrambled by means of user keys.

### 34.2 Embedded Characteristics

- Four Chip Selects Available
- 16-Mbyte Address Space per Chip Select
- 8-bit or 16-bit Data Bus
- Zero Wait State Scrambling/Unscrambling Function with User Key
- Word, Halfword, Byte Transfers
- Byte Write or Byte Select Lines
- Programmable Setup, Pulse And Hold Time for Read Signals per Chip Select
- Programmable Setup, Pulse And Hold Time for Write Signals per Chip Select
- Programmable Data Float Time per Chip Select
- External Wait Request
- Automatic Switch to Slow Clock Mode
- Asynchronous Read in Page Mode Supported: Page Size Ranges from 4 to 32 Bytes
- Register Write Protection

### 34.3 I/O Lines Description

**Table 34-1. I/O Line Description**

| Name      | Description                                | Type   | Active Level |
|-----------|--|--------|--------------|
| NCS[3:0]  | Static Memory Controller Chip Select Lines | Output | Low          |
| NRD       | Read Signal                                | Output | Low          |
| NWR0/NWE  | Write 0/Write Enable Signal                | Output | Low          |
| NWR1/NBS1 | Write 1/Byte 1 Select Signal               | Output | Low          |
| A0/NBS0   | Address Bit 0/Byte 0 Select Signal         | Output | Low          |
| A[23:1]   | Address Bus                                | Output | –            |
| D[15:0]   | Data Bus                                   | I/O    | –            |

.....continued

| Name    | Description                     | Type   | Active Level |
|---------|---------------------------------|--------|--------------|
| NWAIT   | External Wait Signal            | Input  | Low          |
| NANDCS  | NAND Flash Chip Select Line     | Output | Low          |
| NANDOE  | NAND Flash Output Enable        | Output | Low          |
| NANDWE  | NAND Flash Write Enable         | Output | Low          |
| NANDALE | NAND Flash Address Latch Enable | Output | –            |
| NANDCLE | NAND Flash Command Latch Enable | Output | –            |

### 34.4 Multiplexed Signals

**Table 34-2. Static Memory Controller (SMC) Multiplexed Signals**

| Multiplexed Signals |         | Related Function   |
|---------------------|---------|--|
| NWR0                | NWE     | Byte-write or Byte-select access. See " <a href="#">Byte Write Access</a> " and " <a href="#">Byte Select Access</a> " |
| A0                  | NBS0    | 8-bit or 16-bit data bus. See " <a href="#">Data Bus Width</a> "   |
| NWR1                | NBS1    | Byte-write or Byte-select access. See " <a href="#">Byte Write Access</a> " and " <a href="#">Byte Select Access</a> " |
| A22                 | NANDCLE | NAND Flash Command Latch Enable  |
| A21                 | NANDALE | NAND Flash Address Latch Enable  |

### 34.5 Product Dependencies

#### 34.5.1 I/O Lines

The pins used for interfacing the SMC are multiplexed with the PIO lines. The programmer must first program the PIO controller to assign the SMC pins to their peripheral function. If I/O lines of the SMC are not used by the application, they can be used for other purposes by the PIO Controller.

#### 34.5.2 Power Management

The SMC is clocked through the Power Management Controller (PMC), thus the programmer must first configure the PMC to enable the SMC clock.

### 34.6 External Memory Mapping

The SMC provides up to 24 address lines, A[23:0]. This allows each chip select line to address up to 16 Mbytes of memory.

If the physical memory device connected on one chip select is smaller than 16 Mbytes, it wraps around and appears to be repeated within this space. The SMC correctly handles any valid access to the memory device within the page (see the following figure).

**Figure 34-1. Memory Connections for Four External Devices**

### 34.7 Connection to External Devices

#### 34.7.1 Data Bus Width

A data bus width of 8 or 16 bits can be selected for each chip select. This option is controlled by the bit DBW in the Mode register (SMC\_MODE) for the corresponding chip select.

Figure 34-2 shows how to connect a 512-Kbyte × 8-bit memory on NCS2. Figure 34-3 shows how to connect a 512-Kbyte × 16-bit memory on NCS2.

**Figure 34-2. Memory Connection for an 8-bit Data Bus**

**Figure 34-3. Memory Connection for a 16-bit Data Bus**

### 34.7.2 Byte Write or Byte Select Access

Each chip select with a 16-bit data bus can operate with one of two different types of write access: byte write or byte select. This is controlled by the BAT field of the SMC\_MODE register for the corresponding chip select.

#### 34.7.2.1 Byte Write Access

Byte write access is used to connect 2 × 8-bit devices as a 16-bit memory, and supports one write signal per byte of the data bus and a single read signal.

Note that the SMC does not allow boot in Byte write access mode.

For 16-bit devices, the SMC provides NWR0 and NWR1 write signals for respectively Byte0 (lower byte) and Byte1 (upper byte) of a 16-bit bus. One single read signal (NRD) is provided.

#### 34.7.2.2 Byte Select Access

Byte select access is used to connect one 16-bit device. In this mode, read/write operations can be enabled/disabled at byte level. One byte-select line per byte of the data bus is provided. One NRD and one NWE signal control read and write.

For 16-bit devices, the SMC provides NBS0 and NBS1 selection signals for respectively Byte0 (lower byte) and Byte1 (upper byte) of a 16-bit bus.

**Figure 34-4. Connection of 2 × 8-bit Devices on a 16-bit Bus: Byte Write Option**

#### 34.7.2.3 Signal Multiplexing

Depending on the byte access type (BAT), only the byte write signals or the byte select signals are used. To save I/Os at the external bus interface, control signals at the SMC interface are multiplexed. The following table shows signal multiplexing depending on the data bus width and the byte access type.

For 16-bit devices, bit A0 of address is unused. When the Byte Select option is selected, NWR1 is unused. When the Byte Write option is selected, NBS0 is unused.

**Table 34-3. SMC Multiplexed Signal Translation**

| Device Type            | Signal Name |            |           |
|------------------------|-------------|------------|-----------|
|                        | 16-bit Bus  |            | 8-bit Bus |
|                        | 1 x 16-bit  | 2 x 8-bit  | 1 x 8-bit |
| Byte Access Type (BAT) | Byte Select | Byte Write | –         |
| NBS0_A0                | NBS0        | –          | A0        |
| NWE_NWR0               | NWE         | NWR0       | NWE       |
| NBS1_NWR1              | NBS1        | NWR1       | –         |
| A1                     | A1          | A1         | A1        |

### 34.7.3 NAND Flash Support

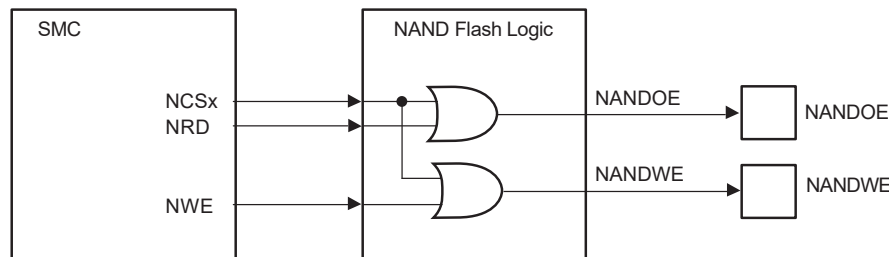

The SMC integrates circuitry that interfaces to NAND Flash devices.

The NAND Flash logic is driven by the SMC. Configuration is done via the SMC\_NFCSx field in the CCFG\_SMCNFCS register in the Bus Matrix. For details on this register, refer to the section “Bus Matrix (MATRIX)” of this datasheet. The external NAND Flash device is accessed via the address space reserved for the chip select programmed.

The user can connect up to four NAND Flash devices with separate chip selects.

The NAND Flash logic drives the read and write command signals of the SMC on the NANDOE and NANDWE signals when the NCSx programmed is active. NANDOE and NANDWE are disabled as soon as the transfer address fails to lie in the NCSx programmed address space.

**Figure 34-5. NAND Flash Signal Multiplexing on SMC Pins**

**Note:** 1. NCSx is active when CCFG\_SMCNFCS.SMC\_NFCSx=1.

**Note:** 2. When the NAND Flash logic is activated, (SMC\_NFCSx=1), the NWE pin can be used only in Peripheral mode (NWE function). If the NWE function is not used for other external memories (SRAM, LCD), it must be configured in one of the following modes:

PIO input with pull-up enabled (default state after reset)  
and PIO output set at level 1.

The address latch enable and command latch enable signals on the NAND Flash device are driven by address bits A22 and A21 of the address bus. Any bit of the address bus can also be used for this purpose. The command, address or data words on the data bus of the NAND Flash device use their own addresses within the NCSx address space (configured in the register CCFG\_SMCNFCS in the Bus Matrix). The chip enable (CE) signal of the device and the ready/busy (R/B) signals are connected to PIO lines. The CE signal then remains asserted even when NAND Flash chip select is not selected, preventing the device from returning to Standby mode. The NANDCS output signal should be used in accordance with the external NAND Flash device type.

Two types of CE behavior exist depending on the NAND Flash device:

- Standard NAND Flash devices require that the CE pin remains asserted low continuously during the read busy period to prevent the device from returning to Standby mode. Since the SMC asserts the NCSx signal high, it is necessary to connect the CE pin of the NAND Flash device to a GPIO line, in order to hold it low during the busy period preceding data read out.

- This restriction has been removed for “CE don’t care” NAND Flash devices. The NCSx signal can be directly connected to the CE pin of the NAND Flash device.

The following figure illustrates both topologies: Standard and “CE don’t care” NAND Flash.

**Figure 34-6. Standard and “CE don’t care” NAND Flash Application Examples**

## 34.8 Application Example

### 34.8.1 Implementation Examples

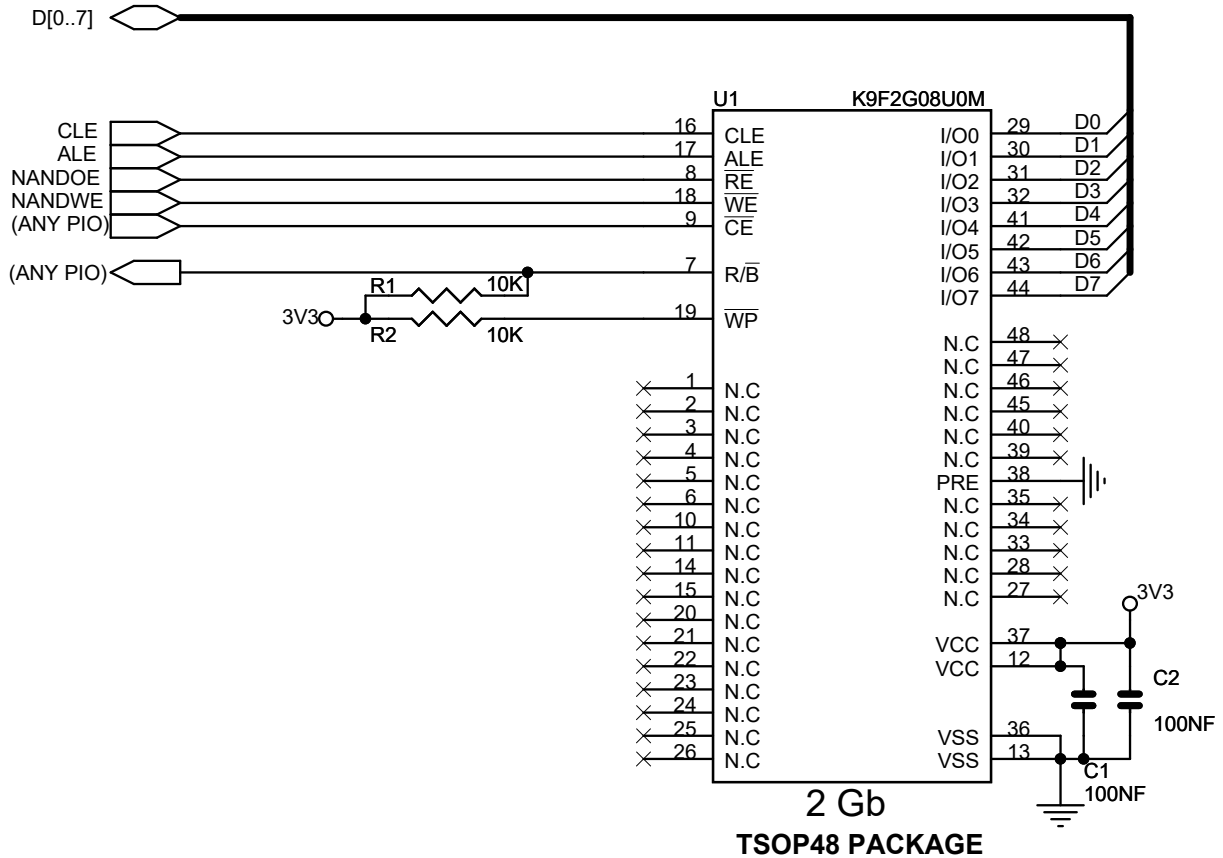

Hardware configurations are given for illustration only. The user should refer to the manufacturer web site to check for memory device availability.

For hardware implementation examples, refer to the evaluation kit schematics for this microcontroller, which show examples of a connection to an LCD module and NAND Flash.

### 34.8.1.1 8-bit NAND Flash

#### Hardware Configuration

Figure 34-7. 8-bit NAND Flash

#### Software Configuration

Perform the following configuration:

1. Select the chip select used to drive the NAND Flash by setting the bit CCFG\_SMCNFC3.SMC\_NFCSx.
2. Reserve A21 / A22 for ALE / CLE functions. Address and Command Latches are controlled by setting the address bits A21 and A22, respectively, during accesses.
3. NANDOE and NANDWE signals are multiplexed with PIO lines. Thus, the dedicated PIOs must be programmed in Peripheral mode in the PIO controller.
4. Configure a PIO line as an input to manage the Ready/Busy signal.
5. Configure SMC CS3 Setup, Pulse, Cycle and Mode according to NAND Flash timings, the data bus width and the system bus frequency.

In this example, the NAND Flash is not addressed as a “CE don’t care”. To address it as a “CE don’t care”, connect NCS3 (if SMC\_NFCS3 is set) to the NAND Flash CE.

### 34.8.1.2 NOR Flash

#### Hardware Configuration

Figure 34-8. NOR Flash

#### Software Configuration

Configure the SMC CS0 Setup, Pulse, Cycle, and Mode, depending on Flash timings and system bus frequency.

## 34.9 Standard Read and Write Protocols

In the following sections, the byte access type is not considered. Byte select lines (NBS0 to NBS1) always have the same timing as the A address bus. NWE represents either the NWE signal in byte select access type or one of the byte write lines (NWR0 to NWR1) in byte write access type. NWR0 to NWR1 have the same timings and protocol as NWE. If D[15:8] are used, they have the same timing as D[7:0]. In the same way, NCS represents one of the NCS[0..3] chip select lines.

### 34.9.1 Read Waveforms

The read cycle is shown in the following figure.

The read cycle starts with the address setting on the memory address bus.

**Figure 34-9. Standard Read Cycle**

### 34.9.1.1 NRD Waveform

The NRD signal is characterized by a setup timing, a pulse width and a hold timing.

- **nrd\_setup**—NRD setup time is defined as the setup of address before the NRD falling edge;
- **nrd\_pulse**—NRD pulse length is the time between NRD falling edge and NRD rising edge;
- **nrd\_hold**—NRD hold time is defined as the hold time of address after the NRD rising edge.

### 34.9.1.2 NCS Waveform

The NCS signal can be divided into a setup time, pulse length and hold time:

- **ncs\_rd\_setup**—NCS setup time is defined as the setup time of address before the NCS falling edge.
- **ncs\_rd\_pulse**—NCS pulse length is the time between NCS falling edge and NCS rising edge;
- **ncs\_rd\_hold**—NCS hold time is defined as the hold time of address after the NCS rising edge.

### 34.9.1.3 Read Cycle

The **NRD\_CYCLE** time is defined as the total duration of the read cycle, i.e., from the time where address is set on the address bus to the point where address may change. The total read cycle time is defined as:

$$\text{NRD\_CYCLE} = \text{NRD\_SETUP} + \text{NRD\_PULSE} + \text{NRD\_HOLD},$$

as well as

$$\text{NRD\_CYCLE} = \text{NCS\_RD\_SETUP} + \text{NCS\_RD\_PULSE} + \text{NCS\_RD\_HOLD}$$

All NRD and NCS timings are defined separately for each chip select as an integer number of Host Clock cycles. The **NRD\_CYCLE** field is common to both the NRD and NCS signals, thus the timing period is of the same duration.

**NRD\_CYCLE**, **NRD\_SETUP**, and **NRD\_PULSE** implicitly define the **NRD\_HOLD** value as:

$$\text{NRD\_HOLD} = \text{NRD\_CYCLE} - \text{NRD\_SETUP} - \text{NRD\_PULSE}$$

**NRD\_CYCLE**, **NCS\_RD\_SETUP**, and **NCS\_RD\_PULSE** implicitly define the **NCS\_RD\_HOLD** value as:

$$\text{NCS\_RD\_HOLD} = \text{NRD\_CYCLE} - \text{NCS\_RD\_SETUP} - \text{NCS\_RD\_PULSE}$$

### 34.9.1.4 Null Delay Setup and Hold

If null setup and hold parameters are programmed for NRD and/or NCS, NRD and NCS remain active continuously in case of consecutive read cycles in the same memory (see the following figure).

**Figure 34-10. No Setup, No Hold on NRD and NCS Read Signals**

### 34.9.1.5 Null Pulse

Programming a null pulse is not permitted. The pulse must be at least set to 1. A null value leads to unpredictable behavior.

### 34.9.2 Read Mode

As NCS and NRD waveforms are defined independently of one other, the SMC needs to know when the read data is available on the data bus. The SMC does not compare NCS and NRD timings to know which signal rises first. The READ\_MODE bit in the SMC\_MODE register of the corresponding chip select indicates which signal of NRD and NCS controls the read operation.

#### 34.9.2.1 Read is Controlled by NRD (SMC\_MODE.READ\_MODE = 1):

The following figure shows the waveforms of a read operation of a typical asynchronous RAM. The read data is available  $t_{PACC}$  after the falling edge of NRD, and turns to 'Z' after the rising edge of NRD. In this case, SMC\_MODE.READ\_MODE must be set to 1 (read is controlled by NRD), to indicate that data is available with the rising edge of NRD. The SMC samples the read data internally on the rising edge of Host Clock that generates the rising edge of NRD, whatever the programmed waveform of NCS may be.

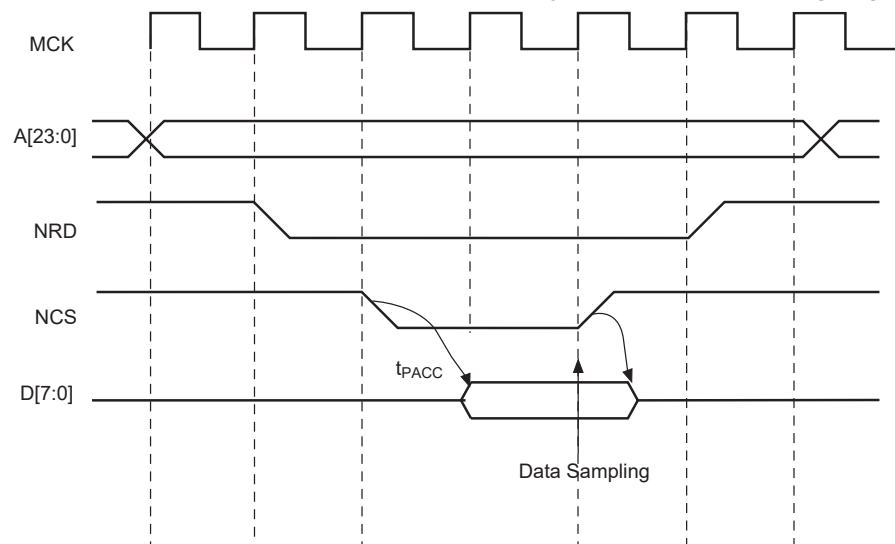

**Figure 34-11. SMC\_MODE.READ\_MODE = 1: Data is sampled by SMC before the rising edge of NRD**

### 34.9.2.2 Read is Controlled by NCS (SMC\_MODE.READ\_MODE = 0)

The following figure shows the typical read cycle of an LCD module. The read data is valid  $t_{PACC}$  after the falling edge of the NCS signal and remains valid until the rising edge of NCS. Data must be sampled when NCS is raised. In this case, the SMC\_MODE.READ\_MODE must be set to 0 (read is controlled by NCS): the SMC internally samples the data on the rising edge of Host Clock that generates the rising edge of NCS, whatever the programmed waveform of NRD may be.

**Figure 34-12. SMC\_MODE.READ\_MODE = 0: Data is Sampled by SMC Before the Rising Edge of NCS**

### 34.9.3 Write Waveforms

The write protocol is similar to the read protocol. It is depicted in [Figure 34-13](#). The write cycle starts with the address setting on the memory address bus.

#### 34.9.3.1 NWE Waveforms

The NWE signal is characterized by a setup timing, a pulse width and a hold timing.

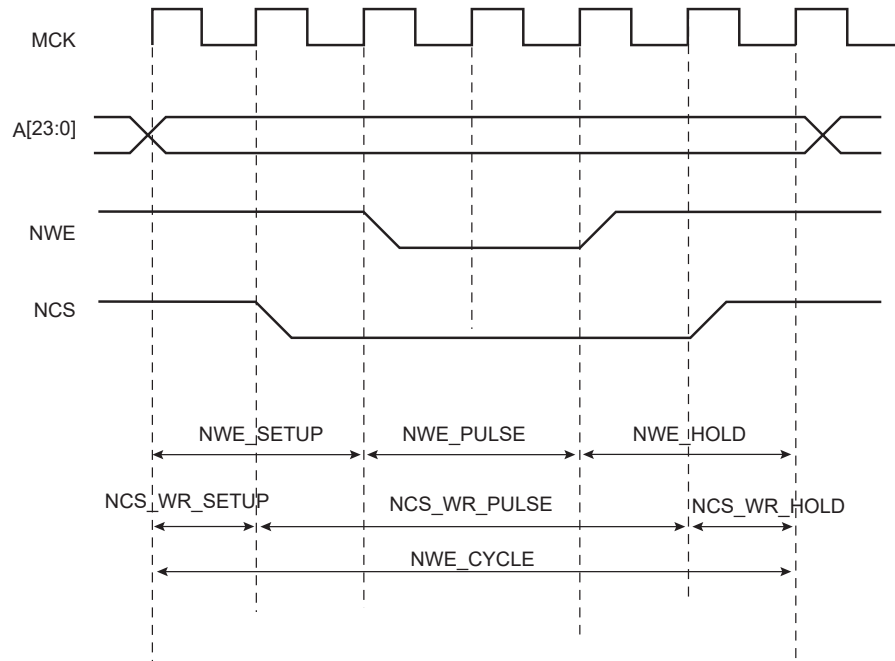

- NWE\_SETUP—the NWE setup time is defined as the setup of address and data before the NWE falling edge;
- NWE\_PULSE—the NWE pulse length is the time between NWE falling edge and NWE rising edge;
- NWE\_HOLD—the NWE hold time is defined as the hold time of address and data after the NWE rising edge.

### 34.9.3.2 NCS Waveforms

The NCS signal waveforms in write operation are not the same that those applied in read operations, but are separately defined:

- ncs\_wr\_setup—the NCS setup time is defined as the setup time of address before the NCS falling edge.
- ncs\_wr\_pulse—the NCS pulse length is the time between NCS falling edge and NCS rising edge;
- ncs\_wr\_hold—the NCS hold time is defined as the hold time of address after the NCS rising edge.

**Figure 34-13. Write Cycle**

### 34.9.3.3 Write Cycle

The write\_cycle time is defined as the total duration of the write cycle; that is, from the time where address is set on the address bus to the point where address may change. The total write cycle time is defined as:

$$\text{NWE\_CYCLE} = \text{NWE\_SETUP} + \text{NWE\_PULSE} + \text{NWE\_HOLD},$$

as well as

$$\text{NWE\_CYCLE} = \text{NCS\_WR\_SETUP} + \text{NCS\_WR\_PULSE} + \text{NCS\_WR\_HOLD}$$

All NWE and NCS (write) timings are defined separately for each chip select as an integer number of Host Clock cycles. The NWE\_CYCLE field is common to both the NWE and NCS signals, thus the timing period is of the same duration.

NWE\_CYCLE, NWE\_SETUP, and NWE\_PULSE implicitly define the NWE\_HOLD value as:

$$\text{NWE\_HOLD} = \text{NWE\_CYCLE} - \text{NWE\_SETUP} - \text{NWE\_PULSE}$$

NWE\_CYCLE, NCS\_WR\_SETUP, and NCS\_WR\_PULSE implicitly define the NCS\_WR\_HOLD value as:

$$\text{NCS\_WR\_HOLD} = \text{NWE\_CYCLE} - \text{NCS\_WR\_SETUP} - \text{NCS\_WR\_PULSE}$$

### 34.9.3.4 Null Delay Setup and Hold

If null setup parameters are programmed for NWE and/or NCS, NWE and/or NCS remain active continuously in case of consecutive write cycles in the same memory (see the following figure). However, for devices that perform write operations on the rising edge of NWE or NCS, such as SRAM, either a setup or a hold must be programmed.

**Figure 34-14. Null Setup and Hold Values of NCS and NWE in Write Cycle**

### 34.9.3.5 Null Pulse

Programming null pulse is not permitted. Pulse must be at least set to 1. A null value leads to unpredictable behavior.

### 34.9.4 Write Mode

The bit `WRITE_MODE` in the `SMC_MODE` register of the corresponding chip select indicates which signal controls the write operation.

#### 34.9.4.1 Write is Controlled by NWE (`SMC.MODE.WRITE_MODE = 1`):

The following figure shows the waveforms of a write operation with `SMC_MODE.WRITE_MODE` set . The data is put on the bus during the pulse and hold steps of the `NWE` signal. The internal data buffers are switched to Output mode after the `NWE_SETUP` time, and until the end of the write cycle, regardless of the programmed waveform on `NCS`.

**Figure 34-15. `SMC_MODE.WRITE_MODE = 1`. Write Operation is Controlled by NWE**

### 34.9.4.2 Write is Controlled by NCS (SMC.MODE.WRITE\_MODE = 0)

The following figure shows the waveforms of a write operation with SMC\_MODE.WRITE\_MODE cleared. The data is put on the bus during the pulse and hold steps of the NCS signal. The internal data buffers are switched to Output mode after the NCS\_WR\_SETUP time, and until the end of the write cycle, regardless of the programmed waveform on NWE.

**Figure 34-16. WRITE\_MODE = 0. Write Operation is Controlled by NCS**

### 34.9.5 Register Write Protection

To prevent any single software error that may corrupt SMC behavior, the registers listed below can be write-protected by setting the WPEN bit in the SMC Write Protection Mode register (SMC\_WPMR).

If a write access in a write-protected register is detected, the WPVS flag in the SMC Write Protection Status register (SMC\_WPSR) is set and the field WPVSR indicates in which register the write access has been attempted.

The WPVS flag is automatically cleared after reading the SSMC\_WPSR.

The following registers can be write-protected:

- "SMC Setup Register"
- "SMC Pulse Register"
- "SMC Cycle Register"
- "SMC Mode Register"
- "SMC Off-chip Memory Scrambling Register"

### 34.9.6 Coding Timing Parameters

All timing parameters are defined for one chip select and are grouped together in one register according to their type.

The SMC\_SETUP register groups the definition of all setup parameters:

- NRD\_SETUP
- NCS\_RD\_SETUP
- NWE\_SETUP
- NCS\_WR\_SETUP

The SMC\_PULSE register groups the definition of all pulse parameters:

- NRD\_PULSE
- NCS\_RD\_PULSE
- NWE\_PULSE
- NCS\_WR\_PULSE

The SMC\_CYCLE register groups the definition of all cycle parameters:

- NRD\_CYCLE

- NWE\_CYCLE

The following table shows how the timing parameters are coded and their permitted range.

**Table 34-4. Coding and Range of Timing Parameters**

| Coded Value | Number of Bits | Effective Value                                    | Permitted Range |  |
|-------------|----------------|--|-----------------|--|
|             |                |  | Coded Value     | Effective Value  |
| setup [5:0] | 6              | $128 \times \text{setup}[5] + \text{setup}[4:0]$   | $0 \leq 31$     | $0 \leq 128+31$  |
| pulse [6:0] | 7              | $256 \times \text{pulse}[6] + \text{pulse}[5:0]$   | $0 \leq 63$     | $0 \leq 256+63$  |
| cycle [8:0] | 9              | $256 \times \text{cycle}[8:7] + \text{cycle}[6:0]$ | $0 \leq 127$    | $0 \leq 256+127$<br>$0 \leq 512+127$<br>$0 \leq 768+127$ |

### 34.9.7 Reset Values of Timing Parameters

The following table provides the default value of timing parameters at reset.

**Table 34-5. Reset Values of Timing Parameters**

| Parameter  | Reset Value | Definition   |
|------------|-------------|--|
| SMC_SETUP  | 0x01010101  | All setup timings are set to 1.  |
| SMC_PULSE  | 0x01010101  | All pulse timings are set to 1.  |
| SMC_CYCLE  | 0x00030003  | The read and write operations continue for 3 Host Clock cycles and provide one hold cycle. |
| WRITE_MODE | 1           | Write is controlled with NWE.  |
| READ_MODE  | 1           | Read is controlled with NRD.   |

### 34.9.8 Usage Restriction

The SMC does not check the validity of the user-programmed parameters. If the sum of SETUP and PULSE parameters is larger than the corresponding CYCLE parameter, this leads to unpredictable behavior of the SMC.

- For read operations:  
Null but positive setup and hold of address and NRD and/or NCS can not be guaranteed at the memory interface because of the propagation delay of these signals through external logic and pads. If positive setup and hold values must be verified, then it is strictly recommended to program non-null values so as to cover possible skews between address, NCS and NRD signals.
- For write operations:  
If a null hold value is programmed on NWE, the SMC can guarantee a positive hold of address and NCS signal after the rising edge of NWE. This is true for SMC\_MODE.WRITE\_MODE = 1 only. See "[Early Read Wait State](#)".
- For read and write operations:  
A null value for pulse parameters is forbidden and may lead to unpredictable behavior.

In read and write cycles, the setup and hold time parameters are defined in reference to the address bus. For external devices that require setup and hold time between NCS and NRD signals (read), or between NCS and NWE signals (write), these setup and hold times must be converted into setup and hold times in reference to the address bus.

## 34.10 Scrambling/Unscrambling Function

The external data bus can be scrambled to protect intellectual property data located in off-chip memories by means of data analysis at the package pin level of either the microcontroller or the memory device.

The scrambling and unscrambling are performed on-the-fly without additional wait states.

The scrambling/unsrambling function can be enabled or disabled by configuring the CSxSE bits in the SMC Off-Chip Memory Scrambling Register (SMC\_OCMS).

When multiple chip selects are handled, the scrambling function per chip select is configurable using the CSxSE bits in the SMC\_OCMS register.

The scrambling method depends on two user-configurable key registers, SMC\_KEY1 and SMC\_KEY2 plus a random value depending on device processing characteristics. These key registers cannot be read. They can be written once after a system reset.

The scrambling user key or the seed for key generation must be securely stored in a reliable non-volatile memory in order to recover data from the off-chip memory. Any data scrambled with a given key cannot be recovered if the key is lost.

### 34.11 Automatic Wait States

Under certain circumstances, the SMC automatically inserts idle cycles between accesses to avoid bus contention or operation conflict.

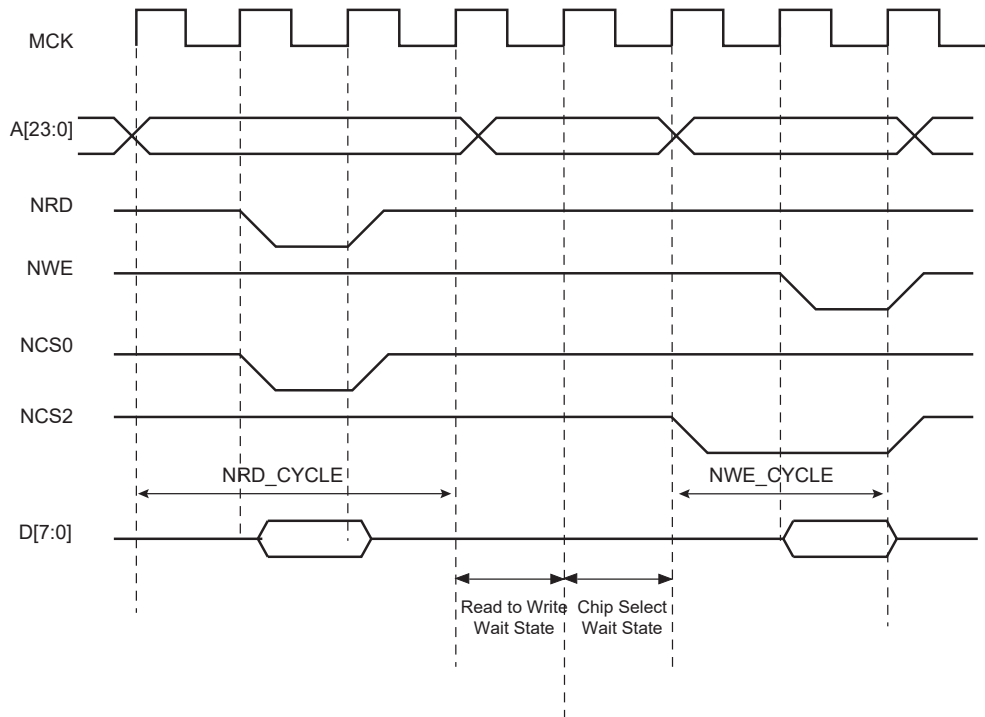

#### 34.11.1 Chip Select Wait States

The SMC always inserts an idle cycle between two transfers on separate Chip Selects. This idle cycle ensures that there is no bus contention between the deactivation of one device and the activation of the next one.

During Chip Select Wait state, all control lines are turned inactive: NWR, NCS[0..3], NRD lines are all set to 1.

The following figure illustrates a Chip Select Wait state between access on Chip Select 0 and Chip Select 2.

**Figure 34-17. Chip Select Wait State between a Read Access on NCS0 and a Write Access on NCS2**

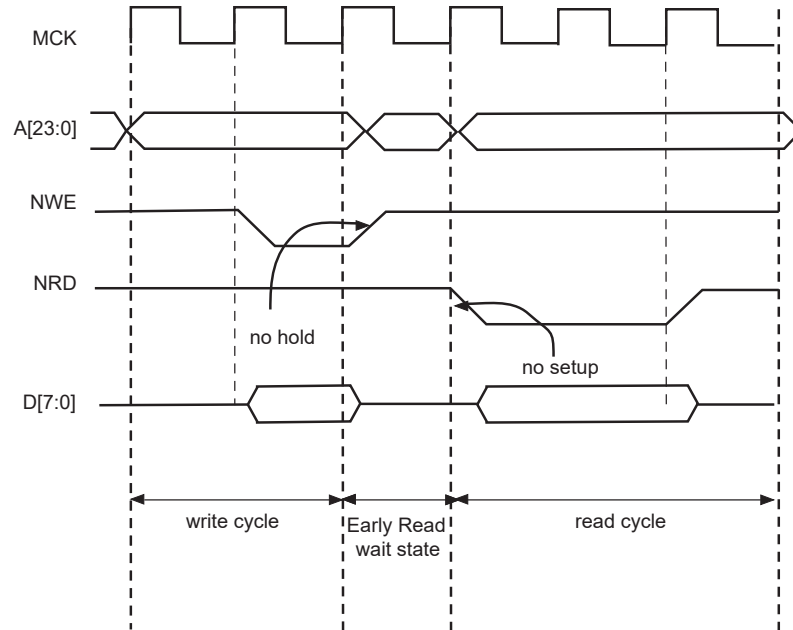

#### 34.11.2 Early Read Wait State

In some cases, the SMC inserts a wait state cycle between a write access and a read access to allow time for the write cycle to end before the subsequent read cycle begins. This wait state is not generated in addition to a chip select wait state. The early read cycle thus only occurs between a write and read access to the same memory device (same chip select).

An early read wait state is automatically inserted if at least one of the following conditions is valid:

- if the write controlling signal has no hold time and the read controlling signal has no setup time (Figure 34-18).
- in NCS Write controlled mode (SMC\_MODE.WRITE\_MODE = 0), if there is no hold timing on the NCS signal and the NCS\_RD\_SETUP parameter is set to 0, regardless of the Read mode (Figure 34-19). The write operation must end with a NCS rising edge. Without an Early Read Wait State, the write operation could not complete properly.
- in NWE controlled mode (SMC\_MODE.WRITE\_MODE = 1) and if there is no hold timing (NWE\_HOLD = 0), the feedback of the write control signal is used to control address, data, and chip select lines. If the external write control signal is not inactivated as expected due to load capacitances, an Early Read Wait State is inserted and address, data and control signals are maintained one more cycle. See Figure 34-20.

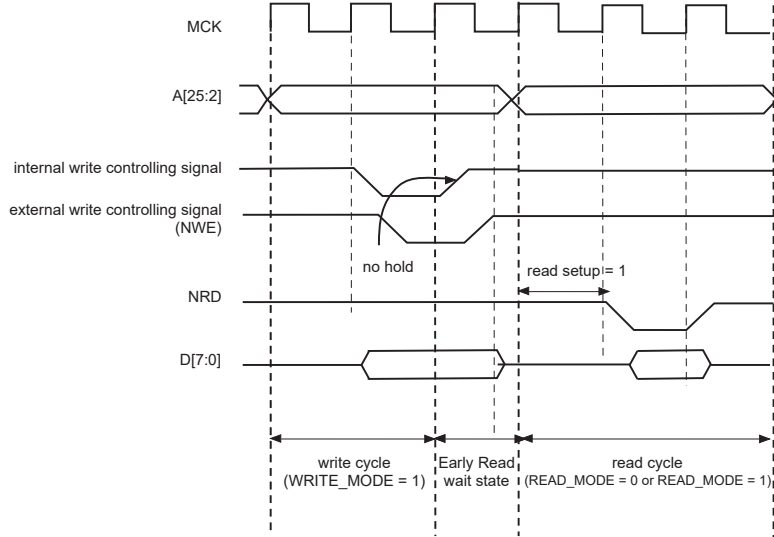

**Figure 34-18. Early Read Wait State: Write with No Hold Followed by Read with No Setup**

**Figure 34-19. Early Read Wait State: NCS-controlled write with no hold followed by a read with no NCS setup**

**Figure 34-20. Early Read Wait State: NWE-controlled write with no hold followed by a read with one set-up cycle**

### 34.11.3 Reload User Configuration Wait State

The user may change any of the configuration parameters by writing the SMC user interface.

When detecting that a new user configuration has been written in the user interface, the SMC inserts a wait state before starting the next access. This “reload user configuration wait state” is used by the SMC to load the new set of parameters to apply to next accesses.

The reload configuration wait state is not applied in addition to the chip select wait state. If accesses before and after re-programming the user interface are made to different devices (chip selects), then one single chip select wait state is applied.

On the other hand, if accesses before and after writing the user interface are made to the same device, a reload configuration wait state is inserted, even if the change does not concern the current chip select.

#### 34.11.3.1 User Procedure

To insert a reload configuration wait state, the SMC detects a write access to any SMC\_MODE register of the user interface. If the user only modifies timing registers (SMC\_SETUP, SMC\_PULSE, SMC\_CYCLE registers) in the user interface, he must validate the modification by writing the SMC\_MODE, even if no change was made on the mode parameters.

The user must not change the configuration parameters of an SMC chip select (Setup, Pulse, Cycle, Mode) if accesses are performed on this CS during the modification. Any change of the chip select parameters, while fetching the code from a memory connected on this CS, may lead to unpredictable behavior. The instructions used to modify the parameters of an SMC chip select can be executed from the internal RAM or from a memory connected to another CS.

#### 34.11.3.2 Slow Clock Mode Transition

A reload configuration wait state is also inserted when the Slow Clock mode is entered or exited, after the end of the current transfer (see “[Slow Clock Mode](#)”).

### 34.11.4 Read to Write Wait State

Due to an internal mechanism, a wait cycle is always inserted between consecutive read and write SMC accesses.

This wait cycle is referred to as a read to write wait state in this document.

This wait cycle is applied in addition to chip select and reload user configuration wait states when they are to be inserted. See [Figure 12-1](#).

### 34.12 Data Float Wait States

Some memory devices are slow to release the external bus. For such devices, it is necessary to add wait states (data float wait states) after a read access:

- before starting a read access to a different external memory
- before starting a write access to the same device or to a different external one.

The data float output time ( $t_{DF}$ ) for each external memory device is programmed in the `SMC_MODE.TDF_CYCLES` field for the corresponding chip select. The value of `SMC_MODE.TDF_CYCLES` indicates the number of data float wait cycles (between 0 and 15) before the external device releases the bus, and represents the time allowed for the data output to go to high impedance after the memory is disabled.

Data float wait states do not delay internal memory accesses. Hence, a single access to an external memory with long  $t_{DF}$  will not slow down the execution of a program from internal memory.

The data float wait states management depends on `SMC_MODE.READ_MODE` and the `SMC_MODE.TDF_MODE` fields for the corresponding chip select.

#### 34.12.1 SMC\_MODE.READ\_MODE

Setting `SMC_MODE.READ_MODE` to 1 indicates to the SMC that the `NRD` signal is responsible for turning off the tri-state buffers of the external memory device. The Data Float Period then begins after the rising edge of the `NRD` signal and lasts `SMC_MODE.TDF_CYCLES` MCK cycles.

When the read operation is controlled by the `NCS` signal (`SMC_MODE.READ_MODE = 0`), the `TDF` field gives the number of MCK cycles during which the data bus remains busy after the rising edge of `NCS`.

[Figure 34-21](#) illustrates the Data Float Period in `NRD`-controlled mode (`SMC_MODE.READ_MODE = 1`), assuming a data float period of 2 cycles (`SMC_MODE.TDF_CYCLES = 2`). [Figure 34-22](#) shows the read operation when controlled by `NCS` (`SMC_MODE.READ_MODE = 0`) and `SMC_MODE.TDF_CYCLES = 3`.

**Figure 34-21. TDF Period in NRD Controlled Read Access (TDF = 2)**

**Figure 34-22. TDF Period in NCS Controlled Read Operation (TDF = 3)**

### 34.12.2 TDF Optimization Enabled (SMC\_MODE.TDF\_MODE = 1)

When SMC\_MODE.TDF\_MODE is set to 1 (TDF optimization is enabled), the SMC takes advantage of the setup period of the next access to optimize the number of wait states cycle to insert.

The following figure shows a read access controlled by NRD, followed by a write access controlled by NWE, on Chip Select 0. Chip Select 0 has been programmed with:

nrd\_hold = 4; SMC\_MODE.read\_mode = 1 (NRD controlled)

nwe\_setup = 3; SMC\_MODE.write\_mode = 1 (NWE controlled)

SMC\_MODE.TDF\_CYCLES = 6; SMC\_MODE.TDF\_MODE = 1 (optimization enabled).

**Figure 34-23. TDF Optimization: No TDF wait states are inserted if the TDF period is over when the next access begins**

### 34.12.3 TDF Optimization Disabled (SMC\_MODE.TDF\_MODE = 0)

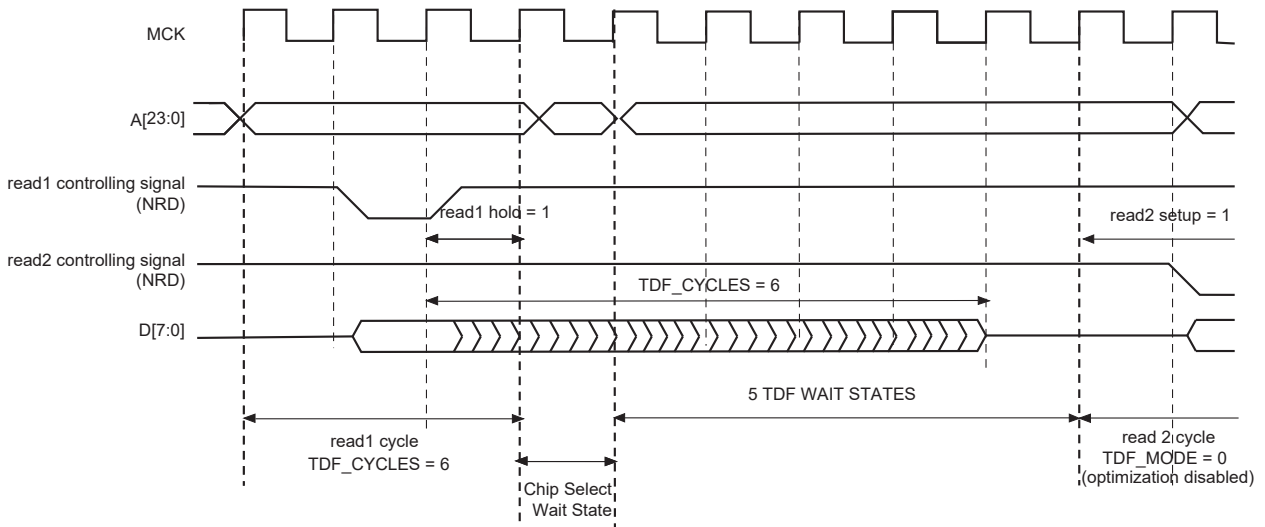

When optimization is disabled, TDF Wait states are inserted at the end of the read transfer, so that the data float period is ended when the second access begins. If the hold period of the read1 controlling signal overlaps the data float period, no additional TDF Wait states will be inserted.

Figure 34-24, Figure 34-25 and Figure 34-26 illustrate the cases:

- read access followed by a read access on another Chip Select,
- read access followed by a write access on another Chip Select,
- read access followed by a write access on the same Chip Select,

with no TDF optimization.

**Figure 34-24. TDF Optimization Disabled (TDF Mode = 0): TDF wait states between 2 read accesses on different chip selects**

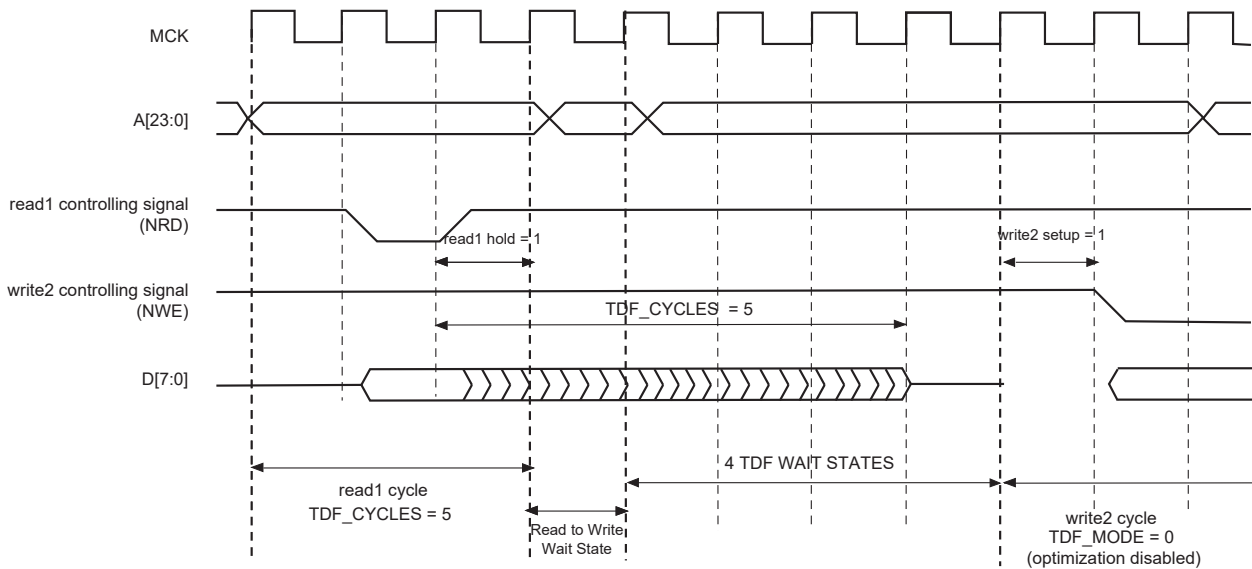

**Figure 34-25. TDF Mode = 0: TDF wait states between a read and a write access on different chip selects**

**Figure 34-26. TDF Mode = 0: TDF wait states between read and write accesses on the same chip select**

### 34.13 External Wait

Any access can be extended by an external device using the NWAIT input signal of the SMC. The SMC\_MODE.EXNW\_MODE field on the corresponding chip select must be set either to “10” (Frozen mode) or “11” (Ready mode). When SMC\_MODE.EXNW\_MODE is set to “00” (disabled), the NWAIT signal is simply ignored on the corresponding chip select. The NWAIT signal delays the read or write operation in regards to the read or write controlling signal, depending on the Read and Write modes of the corresponding chip select.

#### 34.13.1 Restriction

When SMC\_MODE.EXNW\_MODE is enabled, it is mandatory to program at least one hold cycle for the read/write controlling signal. For that reason, the NWAIT signal cannot be used in Page mode (34.15. Asynchronous Page Mode), or in Slow clock mode (“Slow Clock Mode”).

The NWAIT signal is assumed to be a response of the external device to the read/write request of the SMC. Then NWAIT is examined by the SMC only in the pulse state of the read or write controlling signal. The assertion of the NWAIT signal outside the expected period has no impact on SMC behavior.

#### 34.13.2 Frozen Mode

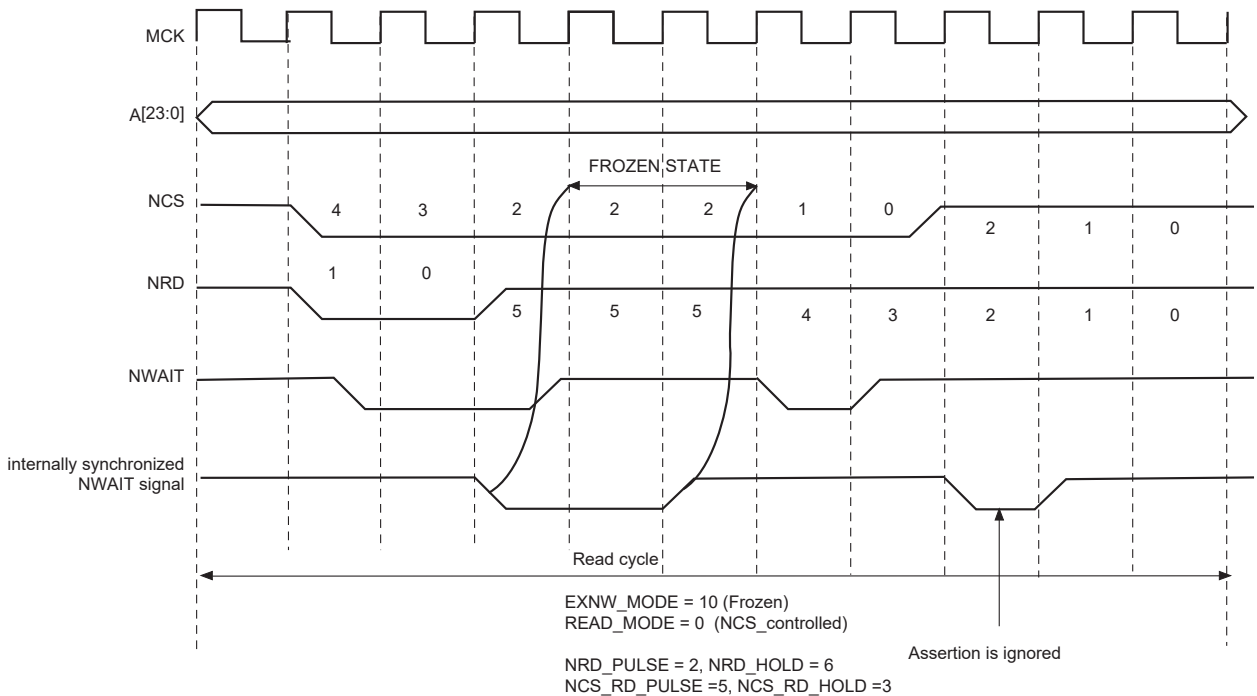

When the external device asserts the NWAIT signal (active low), and after internal synchronization of this signal, the SMC state is frozen, i.e., SMC internal counters are frozen, and all control signals remain unchanged. When the resynchronized NWAIT signal is deasserted, the SMC completes the access, resuming the access from the point where it was stopped. See Figure 34-27. This mode must be selected when the external device uses the NWAIT signal to delay the access and to freeze the SMC.

The assertion of the NWAIT signal outside the expected period is ignored as illustrated in Figure 34-28.

**Figure 34-27. Write Access with NWAIT Assertion in Frozen Mode (SMC\_MODE.EXNW\_MODE = 10)**

**Figure 34-28. Read Access with NWAIT Assertion in Frozen Mode (SMC\_MODE.EXNW\_MODE = 10)**

### 34.13.3 Ready Mode

In Ready mode (SMC\_MODE.EXNW\_MODE = 11), the SMC behaves differently. Normally, the SMC begins the access by down counting the setup and pulse counters of the read/write controlling signal. In the last cycle of the pulse phase, the resynchronized NWAIT signal is examined.

# SAM E70/S70/V70/V71

## Static Memory Controller (SMC)

If asserted, the SMC suspends the access as shown in [Figure 34-29](#) and [Figure 34-30](#). After deassertion, the access is completed: the hold step of the access is performed.

This mode must be selected when the external device uses deassertion of the NWAIT signal to indicate its ability to complete the read or write operation.

If the NWAIT signal is deasserted before the end of the pulse, or asserted after the end of the pulse of the controlling read/write signal, it has no impact on the access length as shown in [Figure 34-30](#).

**Figure 34-29. NWAIT Assertion in Write Access: Ready Mode (SMC\_MODE.EXNW\_MODE = 11)**

**Figure 34-30. NWAIT Assertion in Read Access: Ready Mode (SMC\_MODE.EXNW\_MODE = 11)**

### 34.13.4 NWAIT Latency and Read/Write Timings

There may be a latency between the assertion of the read/write controlling signal and the assertion of the NWAIT signal by the device. The programmed pulse length of the read/write controlling signal must be at least equal to this latency plus the 2 cycles of resynchronization + one cycle. Otherwise, the SMC may enter the hold state of the access without detecting the NWAIT signal assertion. This is true in Frozen mode as well as in Ready mode. This is illustrated in the following figure.

When SMC\_MODE.EXNW\_MODE is enabled (ready or frozen), the user must program a pulse length of the read and write controlling signal of at least:

Minimal pulse length = NWAIT latency + 2 resynchronization cycles + 1 cycle

**Figure 34-31. NWAIT Latency**

### 34.14 Slow Clock Mode

The SMC is able to automatically apply a set of “Slow clock mode” read/write waveforms when an internal signal driven by the Power Management Controller is asserted because MCK has been turned to a very slow clock rate (typically 32kHz clock rate). In this mode, the user-programmed waveforms are ignored and the Slow clock mode waveforms are applied. This mode is provided so as to avoid reprogramming the User Interface with appropriate waveforms at a very slow clock rate. When activated, the Slow clock mode is active on all chip selects.

#### 34.14.1 Slow Clock Mode Waveforms

Figure 34-32 illustrates the read and write operations in Slow Clock mode. They are valid on all Chip Selects. Table 34-6 indicates the value of read and write parameters in Slow Clock mode.

**Figure 34-32. Read/Write Cycles in Slow Clock Mode**

**Table 34-6. Read and Write Timing Parameters in Slow Clock Mode**

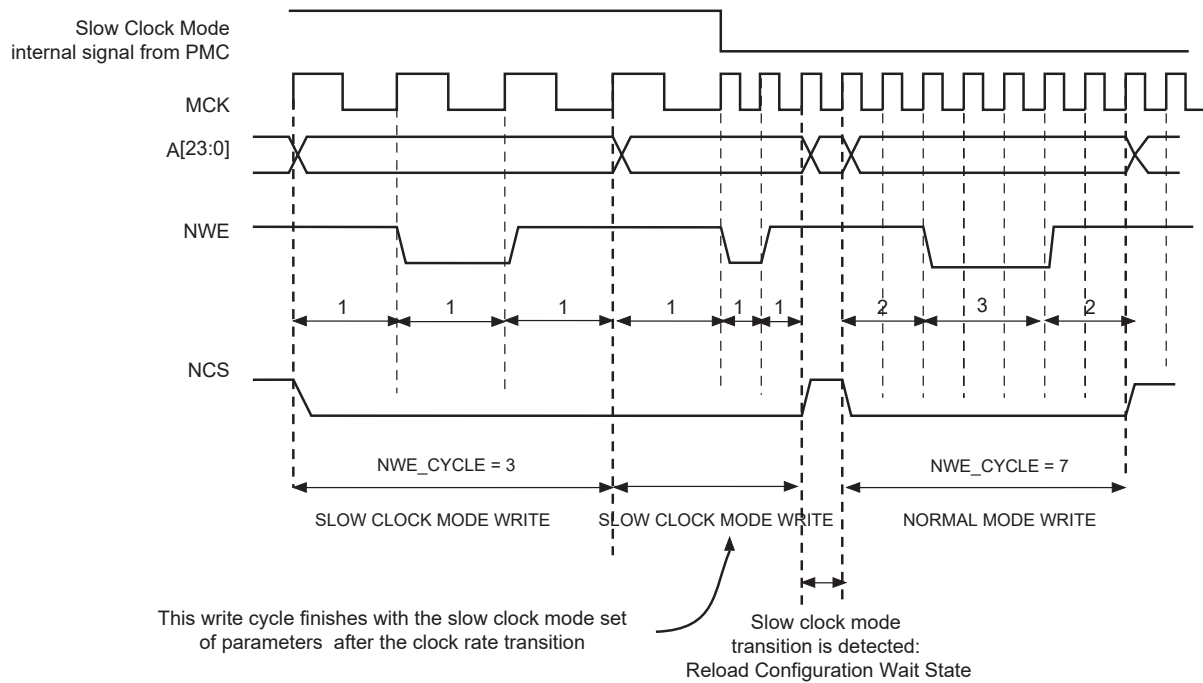

| Read Parameters | Duration (cycles) | Write Parameters | Duration (cycles) |
|-----------------|-------------------|------------------|-------------------|
| NRD_SETUP       | 1                 | NWE_SETUP        | 1                 |
| NRD_PULSE       | 1                 | NWE_PULSE        | 1                 |
| NCS_RD_SETUP    | 0                 | NCS_WR_SETUP     | 0                 |
| NCS_RD_PULSE    | 2                 | NCS_WR_PULSE     | 3                 |
| NRD_CYCLE       | 2                 | NWE_CYCLE        | 3                 |

### 34.14.2 Switching from (to) Slow Clock Mode to (from) Normal Mode

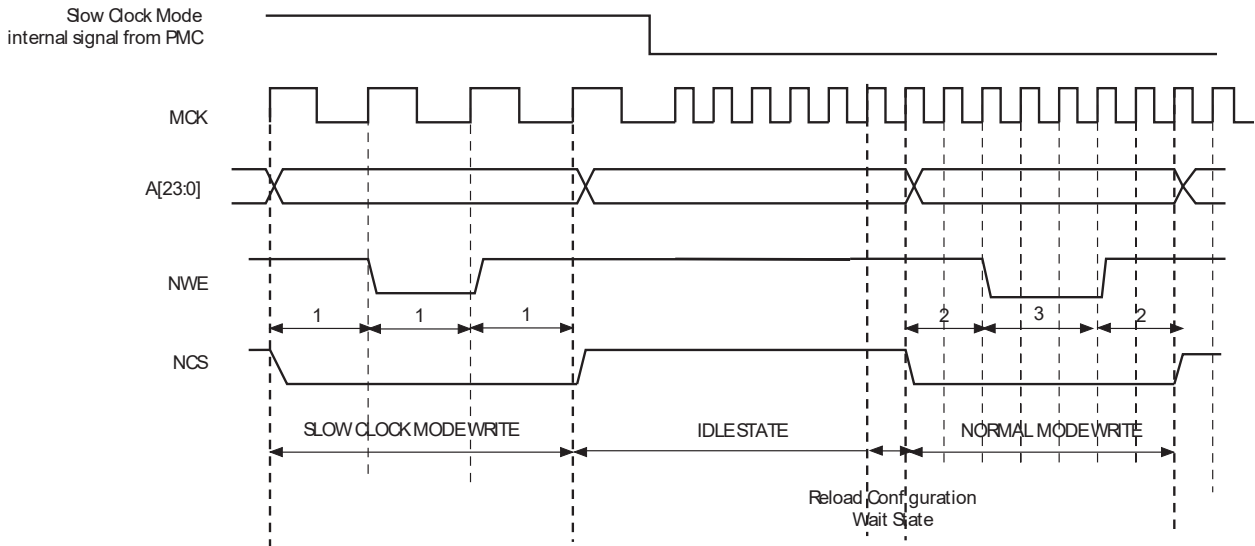

When switching from Slow clock mode to Normal mode, the current Slow clock mode transfer is completed at a high clock rate, with the set of Slow clock mode parameters (see Figure 34-33). The external device may not be fast enough to support such timings.

Figure 34-34 illustrates the recommended procedure to switch from one mode to the other.

**Figure 34-33. Clock Rate Transition Occurs while the SMC is Performing a Write Operation**

**Figure 34-34. Recommended Procedure to Switch from Slow Clock Mode to Normal Mode or from Normal Mode to Slow Clock Mode**

### 34.15 Asynchronous Page Mode

The SMC supports asynchronous burst reads in Page mode, provided that the Page mode is enabled (SMC\_MODE.PMEN =1). The page size must be configured in the SMC\_MODE register (PS field) to 4, 8, 16 or 32 bytes.

The page defines a set of consecutive bytes into memory. A 4-byte page (resp. 8-, 16-, 32-byte page) is always aligned to 4-byte boundaries (resp. 8-, 16-, 32-byte boundaries) of memory. The MSB of data address defines the address of the page in memory, the LSB of address define the address of the data in the page as detailed in the following table.

With Page mode memory devices, the first access to one page ( $t_{pa}$ ) takes longer than the subsequent accesses to the page ( $t_{sa}$ ) as shown in [Page Mode Read Protocol](#). When in Page mode, the SMC enables the user to define different read timings for the first access within one page, and next accesses within the page.

**Table 34-7. Page Address and Data Address within a Page**

| Page Size | Page Address (see Note) | Data Address in the Page |
|-----------|-------------------------|--------------------------|
| 4 bytes   | A[23:2]                 | A[1:0]                   |
| 8 bytes   | A[23:3]                 | A[2:0]                   |
| 16 bytes  | A[23:4]                 | A[3:0]                   |
| 32 bytes  | A[23:5]                 | A[4:0]                   |

**Note:** “A” denotes the address bus of the memory device.

#### 34.15.1 Protocol and Timings in Page Mode

The following figure shows the NRD and NCS timings in Page mode access.

**Figure 34-35. Page Mode Read Protocol (Address MSB and LSB are defined in Table 34-7)**

The NRD and NCS signals are held low during all read transfers, whatever the programmed values of the setup and hold timings in the User Interface may be. Moreover, the NRD and NCS timings are identical. The pulse length of the first access to the page is defined with the NCS\_RD\_PULSE field of the SMC\_PULSE register. The pulse length of subsequent accesses within the page are defined using the NRD\_PULSE parameter.

In Page mode, the programming of the read timings is described in the following table:

**Table 34-8. Programming of Read Timings in Page Mode**

| Parameter    | Value           | Definition                                      |
|--------------|-----------------|---|
| READ_MODE    | 'x'             | No impact.                                      |
| NCS_RD_SETUP | 'x'             | No impact.                                      |
| NCS_RD_PULSE | t <sub>pa</sub> | Access time of first access to the page.        |
| NRD_SETUP    | 'x'             | No impact.                                      |
| NRD_PULSE    | t <sub>sa</sub> | Access time of subsequent accesses in the page. |
| NRD_CYCLE    | 'x'             | No impact.                                      |

The SMC does not check the coherency of timings. It will always apply the NCS\_RD\_PULSE timings as page access timing (t<sub>pa</sub>) and the NRD\_PULSE for accesses to the page (t<sub>sa</sub>), even if the programmed value for t<sub>pa</sub> is shorter than the programmed value for t<sub>sa</sub>.

### 34.15.2 Page Mode Restriction

The Page mode is not compatible with the use of the NWAIT signal. Using the Page mode and the NWAIT signal may lead to unpredictable behavior.

### 34.15.3 Sequential and Non-sequential Accesses

If the chip select and the MSB of addresses as defined in Table 34-7 are identical, then the current access lies in the same page as the previous one, and no page break occurs.

Using this information, all data within the same page, sequential or not sequential, are accessed with a minimum access time (t<sub>sa</sub>). The following figure illustrates access to an 8-bit memory device in Page mode, with 8-byte pages. Access to D1 causes a page access with a long access time (t<sub>pa</sub>). Accesses to D3 and D7, though they are not sequential accesses, only require a short access time (t<sub>sa</sub>).

If the MSB of addresses are different, the SMC performs the access of a new page. In the same way, if the chip select is different from the previous access, a page break occurs. If two sequential accesses are made to the Page mode memory, but separated by an other internal or external peripheral access, a page break occurs on the second access because the chip select of the device was deasserted between both accesses.

**Figure 34-36. Access to Non-Sequential Data within the Same Page**

### 34.16.1 Static Memory Controller (SMC) User Interface

The SMC is programmed using the registers listed in the following table. For each Chip Select, a set of four registers is used to program the parameters of the external device connected on it. In the Register Summary, “CS\_number” denotes the Chip Select number. 16 bytes (0x10) are required per Chip Select.

### 34.16.1.1 SMC Setup Register

**Name:** SMC\_SETUP  
**Offset:** 0x00 + n\*0x10 [n=0..3]  
**Reset:** 0x01010101  
**Property:** R/W

This register can only be written if the WPEN bit is cleared in the [“SMC Write Protection Mode Register”](#).

|        |    |    |                   |     |     |     |     |     |

| Access |    |    | R/W               | R/W | R/W | R/W | R/W | R/W |
| Reset  |    |    | 0                 | 0   | 0   | 0   | 0   | 1   |

**Bits 29:24 – NCS\_RD\_SETUP[5:0]** NCS Setup Length in READ Access

In read access, the NCS signal setup length is defined as:  
 NCS setup length = (128\* NCS\_RD\_SETUP[5] + NCS\_RD\_SETUP[4:0]) clock cycles

**Bits 21:16 – NRD\_SETUP[5:0]** NRD Setup Length

The NRD signal setup length is defined in clock cycles as:  
 NRD setup length = (128\* NRD\_SETUP[5] + NRD\_SETUP[4:0]) clock cycles

**Bits 13:8 – NCS\_WR\_SETUP[5:0]** NCS Setup Length in WRITE Access

In write access, the NCS signal setup length is defined as:  
 NCS setup length = (128\* NCS\_WR\_SETUP[5] + NCS\_WR\_SETUP[4:0]) clock cycles

**Bits 5:0 – NWE\_SETUP[5:0]** NWE Setup Length

The NWE signal setup length is defined as:  
 NWE setup length = (128\* NWE\_SETUP[5] + NWE\_SETUP[4:0]) clock cycles

### 34.16.1.2 SMC Pulse Register

**Name:** SMC\_PULSE  
**Offset:** 0x04 + n\*0x10 [n=0..3]  
**Reset:** 0x01010101  
**Property:** R/W

This register can only be written if the WPEN bit is cleared in the “SMC Write Protection Mode Register”.

#### Bits 30:24 – NCS\_RD\_PULSE[6:0] NCS Pulse Length in READ Access

In standard read access, the NCS signal pulse length is defined as:  

$$\text{NCS pulse length} = (256 * \text{NCS\_RD\_PULSE}[6] + \text{NCS\_RD\_PULSE}[5:0]) \text{ clock cycles}$$
 The NCS pulse length must be at least 1 clock cycle.  
 In Page mode read access, the NCS\_RD\_PULSE parameter defines the duration of the first access to one page.

#### Bits 22:16 – NRD\_PULSE[6:0] NRD Pulse Length

In standard read access, the NRD signal pulse length is defined in clock cycles as:  

$$\text{NRD pulse length} = (256 * \text{NRD\_PULSE}[6] + \text{NRD\_PULSE}[5:0]) \text{ clock cycles}$$
 The NRD pulse length must be at least 1 clock cycle.  
 In Page mode read access, the NRD\_PULSE parameter defines the duration of the subsequent accesses in the page.

#### Bits 14:8 – NCS\_WR\_PULSE[6:0] NCS Pulse Length in WRITE Access

In write access, the NCS signal pulse length is defined as:  

$$\text{NCS pulse length} = (256 * \text{NCS\_WR\_PULSE}[6] + \text{NCS\_WR\_PULSE}[5:0]) \text{ clock cycles}$$
 The NCS pulse length must be at least 1 clock cycle.

#### Bits 6:0 – NWE\_PULSE[6:0] NWE Pulse Length

The NWE signal pulse length is defined as:  

$$\text{NWE pulse length} = (256 * \text{NWE\_PULSE}[6] + \text{NWE\_PULSE}[5:0]) \text{ clock cycles}$$
 The NWE pulse length must be at least 1 clock cycle.

### 34.16.1.3 SMC Cycle Register

**Name:** SMC\_CYCLE  
**Offset:** 0x08 + n\*0x10 [n=0..3]  
**Reset:** 0x00030003  
**Property:** R/W

This register can only be written if the WPEN bit is cleared in the “SMC Write Protection Mode Register”.

|        |                |     |     |     |     |     |     |              |
|--------|----------------|-----|-----|-----|-----|-----|-----|--------------|
| Bit    | 31             | 30  | 29  | 28  | 27  | 26  | 25  | 24           |
|        |                |     |     |     |     |     |     | NRD_CYCLE[8] |
| Access |                |     |     |     |     |     |     | R/W          |
| Reset  |                |     |     |     |     |     |     | 0            |
|        |                |     |     |     |     |     |     |              |
| Bit    | 23             | 22  | 21  | 20  | 19  | 18  | 17  | 16           |
|        | NRD_CYCLE[7:0] |     |     |     |     |     |     |              |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W          |

|        |                |     |     |     |     |     |     |              |
| Bit    | 15             | 14  | 13  | 12  | 11  | 10  | 9   | 8            |
|        |                |     |     |     |     |     |     | NWE_CYCLE[8] |
| Access |                |     |     |     |     |     |     | R/W          |
| Reset  |                |     |     |     |     |     |     | 0            |
|        |                |     |     |     |     |     |     |              |
| Bit    | 7              | 6   | 5   | 4   | 3   | 2   | 1   | 0            |
|        | NWE_CYCLE[7:0] |     |     |     |     |     |     |              |
| Access | R/W            | R/W | R/W | R/W | R/W | R/W | R/W | R/W          |
| Reset  | 0              | 0   | 0   | 0   | 0   | 0   | 1   | 1            |

**Bits 24:16 – NRD\_CYCLE[8:0] Total Read Cycle Length**

The total read cycle length is the total duration in clock cycles of the read cycle. It is equal to the sum of the setup, pulse and hold steps of the NRD and NCS signals. It is defined as:  
 Read cycle length = (NRD\_CYCLE[8:7]\*256 + NRD\_CYCLE[6:0]) clock cycles

**Bits 8:0 – NWE\_CYCLE[8:0] Total Write Cycle Length**

The total write cycle length is the total duration in clock cycles of the write cycle. It is equal to the sum of the setup, pulse and hold steps of the NWE and NCS signals. It is defined as:  
 Write cycle length = (NWE\_CYCLE[8:7]\*256 + NWE\_CYCLE[6:0]) clock cycles

# SAM E70/S70/V70/V71

## Static Memory Controller (SMC)

### 34.16.1.4 SMC Mode Register

**Name:** SMC\_MODE  
**Offset:** 0x0C + n\*0x10 [n=0..3]  
**Reset:** 0x10001003  
**Property:** R/W

This register can only be written if the WPEN bit is cleared in the “SMC Write Protection Mode Register”.

The user must confirm the SMC configuration by writing any one of the SMC\_MODE registers.

|        |    |    |                |    |                 |    |            |           |
|--------|----|----|----------------|----|-----------------|----|------------|-----------|
| Bit    | 31 | 30 | 29             | 28 | 27              | 26 | 25         | 24        |
|        |    |    | PS[1:0]        |    |                 |    | PMEN       |           |

| Bit    | 15 | 14 | 13             | 12 | 11              | 10 | 9          | 8         |
|        |    |    | DBW            |    |                 |    | BAT        |           |
| Access |    |    | R/W            |    |                 |    | R/W        |           |
| Reset  |    |    | R/W            |    |                 |    | R/W        |           |
|        |    |    |                |    |                 |    |            |           |
| Bit    | 7  | 6  | 5              | 4  | 3               | 2  | 1          | 0         |
|        |    |    | EXNW_MODE[1:0] |    |                 |    | WRITE_MODE | READ_MODE |
| Access |    |    | R/W            |    |                 |    | R/W        | R/W       |
| Reset  |    |    | R/W            |    |                 |    | R/W        | R/W       |

#### Bits 29:28 – PS[1:0] Page Size

If page mode is enabled, this field indicates the size of the page in bytes.

| Value | Name    | Description  |
|-------|---------|--------------|
| 0     | 4_BYTE  | 4-byte page  |
| 1     | 8_BYTE  | 8-byte page  |
| 2     | 16_BYTE | 16-byte page |
| 3     | 32_BYTE | 32-byte page |

#### Bit 24 – PMEN Page Mode Enabled

| Value | Description   |
|-------|---|
| 0     | Standard read is applied.   |
| 1     | Asynchronous burst read in page mode is applied on the corresponding chip select. |

#### Bit 20 – TDF\_MODE TDF Optimization

| Value | Description   |
|-------|---|
| 0     | TDF optimization disabled—the number of TDF wait states is inserted before the next access begins.                        |
| 1     | TDF optimization enabled—the number of TDF wait states is optimized using the setup period of the next read/write access. |

#### Bits 19:16 – TDF\_CYCLES[3:0] Data Float Time

This field gives the integer number of clock cycles required by the external device to release the data after the rising edge of the read controlling signal. The SMC always provide one full cycle of bus turnaround after the TDF\_CYCLES period. The external bus cannot be used by another chip select during TDF\_CYCLES + 1 cycles. From 0 up to 15 TDF\_CYCLES can be set.

#### Bit 12 – DBW Data Bus Width

# SAM E70/S70/V70/V71

## Static Memory Controller (SMC)

| Value | Name   | Description     |
|-------|--------|-----------------|
| 0     | 8_BIT  | 8-bit Data Bus  |
| 1     | 16_BIT | 16-bit Data Bus |

### Bit 8 – BAT Byte Access Type

This field is used only if DBW defines a 16-bit data bus.

| Value | Name        | Description   |
|-------|-------------|---|
| 0     | BYTE_SELECT | Byte select access type:<br>- Write operation is controlled using NCS, NWE, NBS0, NBS1.<br>- Read operation is controlled using NCS, NRD, NBS0, NBS1. |
| 1     | BYTE_WRITE  | Byte write access type:<br>- Write operation is controlled using NCS, NWR0, NWR1.<br>- Read operation is controlled using NCS and NRD.                |

### Bits 5:4 – EXNW\_MODE[1:0] NWAIT Mode

The NWAIT signal is used to extend the current read or write signal. It is only taken into account during the pulse phase of the read and write controlling signal. When the use of NWAIT is enabled, at least one cycle hold duration must be programmed for the read and write controlling signal.

| Value | Name     | Description   |
|-------|----------|---|
| 0     | DISABLED | Disabled—The NWAIT input signal is ignored on the corresponding chip select.  |
| 1     |          | Reserved  |
| 2     | FROZEN   | Frozen Mode—If asserted, the NWAIT signal freezes the current read or write cycle. After deassertion, the read/write cycle is resumed from the point where it was stopped.  |
| 3     | READY    | Ready Mode—The NWAIT signal indicates the availability of the external device at the end of the pulse of the controlling read or write signal, to complete the access. If high, the access normally completes. If low, the access is extended until NWAIT returns high. |

### Bit 1 – WRITE\_MODE Write Mode

| Value | Description  |
|-------|--|
| 0     | The write operation is controlled by the NCS signal.<br>– If TDF optimization is enabled (TDF_MODE =1), TDF wait states will be inserted after the setup of NCS. |
| 1     | The write operation is controlled by the NWE signal.<br>– If TDF optimization is enabled (TDF_MODE =1), TDF wait states will be inserted after the setup of NWE. |

### Bit 0 – READ\_MODE Read Mode

| Value | Description  |
|-------|--|
| 0     | The read operation is controlled by the NCS signal.<br>– If TDF cycles are programmed, the external bus is marked busy after the rising edge of NCS.<br>– If TDF optimization is enabled (TDF_MODE =1), TDF wait states are inserted after the setup of NCS. |
| 1     | The read operation is controlled by the NRD signal.<br>– If TDF cycles are programmed, the external bus is marked busy after the rising edge of NRD.<br>– If TDF optimization is enabled (TDF_MODE =1), TDF wait states are inserted after the setup of NRD. |

### 34.16.1.5 SMC Off-Chip Memory Scrambling Register

**Name:** SMC\_OCMS  
**Offset:** 0x80  
**Reset:** 0x00000000  
**Property:** Read/Write

**Note:** This register can only be written if the WPEN bit is cleared in the SMC Write Protection Mode Register (34.16.1.8. [SMC\\_WPMR](#)).

|        |    |    |    |    |       |       |       |       |
|--------|----|----|----|----|-------|-------|-------|-------|
| Bit    | 31 | 30 | 29 | 28 | 27    | 26    | 25    | 24    |
| Access |    |    |    |    |       |       |       |       |
| Reset  |    |    |    |    |       |       |       |       |
| Bit    | 23 | 22 | 21 | 20 | 19    | 18    | 17    | 16    |
| Access |    |    |    |    |       |       |       |       |
| Reset  |    |    |    |    |       |       |       |       |
| Bit    | 15 | 14 | 13 | 12 | 11    | 10    | 9     | 8     |
| Access |    |    |    |    | CS3SE | CS2SE | CS1SE | CS0SE |
| Reset  |    |    |    |    | R/W   | R/W   | R/W   | R/W   |
| Reset  |    |    |    |    | 0     | 0     | 0     | 0     |
| Bit    | 7  | 6  | 5  | 4  | 3     | 2     | 1     | 0     |
| Access |    |    |    |    |       |       |       | SMSE  |
| Reset  |    |    |    |    |       |       |       | R/W   |
| Reset  |    |    |    |    |       |       |       | 0     |

#### Bits 8, 9, 10, 11 – CSSE Chip Select x Scrambling Enable

| Value | Description                 |
|-------|-----------------------------|
| 0     | Disable scrambling for CSx. |
| 1     | Enable scrambling for CSx.  |

#### Bit 0 – SMSE Static Memory Controller Scrambling Enable

| Value | Description                        |
|-------|------------------------------------|
| 0     | Disable scrambling for SMC access. |
| 1     | Enable scrambling for SMC access.  |

### 34.16.1.6 SMC Off-Chip Memory Scrambling Key1 Register

**Name:** SMC\_KEY1  
**Offset:** 0x84  
**Reset:** 0x00000000  
**Property:** Write-once

**Note:**

1. 'Write-once' access indicates that the first write access after a system reset prevents any further modification of the value of this register.

|        |       |             |    |    |    |    |    |    |    |
|--------|-------|-------------|----|----|----|----|----|----|----|
|        | Bit   | 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        |       | KEY1[31:24] |    |    |    |    |    |    |    |
| Access | Reset | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|        | Bit   | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        |       | KEY1[23:16] |    |    |    |    |    |    |    |
| Access | Reset | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|        | Bit   | 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        |       | KEY1[15:8]  |    |    |    |    |    |    |    |
| Access | Reset | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|        | Bit   | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        |       | KEY1[7:0]   |    |    |    |    |    |    |    |
| Access | Reset | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Bits 31:0 – KEY1[31:0] Off-Chip Memory Scrambling (OCMS) Key Part 1**

When off-chip memory scrambling is enabled, KEY1 and KEY2 values determine data scrambling.

### 34.16.1.7 SMC Off-Chip Memory Scrambling Key2 Register

**Name:** SMC\_KEY2  
**Offset:** 0x88  
**Reset:** 0x00000000  
**Property:** Write-once

**Note:** 'Write-once' access indicates that the first write access after a system reset prevents any further modification of the value of this register.

|        |             |    |    |    |    |    |    |    |
|--------|-------------|----|----|----|----|----|----|----|
| Bit    | 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|        | KEY2[31:24] |    |    |    |    |    |    |    |
| Access |             |    |    |    |    |    |    |    |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|        |             |    |    |    |    |    |    |    |
| Bit    | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|        | KEY2[23:16] |    |    |    |    |    |    |    |
| Access |             |    |    |    |    |    |    |    |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|        |             |    |    |    |    |    |    |    |
| Bit    | 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
|        | KEY2[15:8]  |    |    |    |    |    |    |    |
| Access |             |    |    |    |    |    |    |    |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
|        |             |    |    |    |    |    |    |    |
| Bit    | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|        | KEY2[7:0]   |    |    |    |    |    |    |    |
| Access |             |    |    |    |    |    |    |    |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

**Bits 31:0 – KEY2[31:0]** Off-Chip Memory Scrambling (OCMS) Key Part 2

When off-chip memory scrambling is enabled, KEY1 and KEY2 values determine data scrambling.

# SAM E70/S70/V70/V71

## Static Memory Controller (SMC)

### 34.16.1.8 SMC Write Protection Mode Register

**Name:** SMC\_WPMR  
**Offset:** 0xE4  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |              |     |     |     |     |     |     |     |

#### Bits 31:8 – WPKEY[23:0] Write Protection Key

| Value    | Name   | Description  |
|----------|--------|--|
| 0x534D43 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit. Always reads as 0. |

#### Bit 0 – WPEN Write Protect Enable

See ["Register Write Protection"](#) for the list of registers that can be write-protected.

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x534D43 ("SMC" in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x534D43 ("SMC" in ASCII).  |

### 34.16.1.9 SMC Write Protection Status Register

**Name:** SMC\_WPSR  
**Offset:** 0xE8  
**Reset:** 0x00000000  
**Property:** Read-only

|        |             |    |    |    |    |    |    |      |
|--------|-------------|----|----|----|----|----|----|------|
| Bit    | 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24   |
|        |             |    |    |    |    |    |    |      |
| Access |             |    |    |    |    |    |    |      |
| Reset  |             |    |    |    |    |    |    |      |
|        |             |    |    |    |    |    |    |      |
| Bit    | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16   |
|        | WPVSR[15:8] |    |    |    |    |    |    |      |
| Access | R           | R  | R  | R  | R  | R  | R  | R    |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0    |
|        |             |    |    |    |    |    |    |      |
| Bit    | 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8    |
|        | WPVSR[7:0]  |    |    |    |    |    |    |      |
| Access | R           | R  | R  | R  | R  | R  | R  | R    |
| Reset  | 0           | 0  | 0  | 0  | 0  | 0  | 0  | 0    |
|        |             |    |    |    |    |    |    |      |
| Bit    | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
|        |             |    |    |    |    |    |    | WPVS |
| Access |             |    |    |    |    |    |    | R    |
| Reset  |             |    |    |    |    |    |    | 0    |

**Bits 23:8 – WPVSR[15:0]** Write Protection Violation Source

When WPVS = 1, WPVSR indicates the register address offset at which a write access has been attempted.

**Bit 0 – WPVS** Write Protection Violation Status

| Value | Description  |
|-------|--|
| 0     | No write protection violation has occurred since the last read of the SMC_WPSR register.   |
| 1     | A write protection violation has occurred since the last read of the SMC_WPSR register. If this violation is an unauthorized attempt to write a protected register, the associated violation is reported into field WPVSR. |

## **35. DMA Controller (XDMAC)**

### **35.1 Description**

The DMA Controller (XDMAC) is a -protocol central direct memory access controller. It performs peripheral data transfer and memory move operations over one or two bus ports through the unidirectional communication channel. Each channel is fully programmable and provides both peripheral or memory-to-memory transfers. The channel features are configurable at implementation.

### **35.2 Embedded Characteristics**

- Host Interfaces
- DMA Channels
- Hardware Requests
- Embedded FIFO
- Supports Peripheral-to-Memory, Memory-to-Peripheral, or Memory-to-Memory Transfer Operations
- Peripheral DMA Operation Runs on Bytes (8-bit), Half-Word (16-bit) and Word (32-bit)
- Memory DMA Operation Runs on Bytes (8 bit), Half-Word (16-bit) and Word (32 -bit)
- Supports Hardware and Software Initiated Transfers
- Supports Linked List Operations
- Supports Incrementing or Fixed Addressing Mode
- Supports Programmable Independent Data Striding for Source and Destination
- Supports Programmable Independent Microblock Striding for Source and Destination
- Configurable Priority Group and Arbitration Policy
- Programmable Burst Length
- Configuration Interface Accessible through APB Interface
- XDMAC Architecture Includes Multiport FIFO
- Supports Multiple View Channel Descriptor
- Automatic Flush of Channel Trailing Bytes
- Automatic Coarse-Grain and Fine-Grain Clock Gating
- Hardware Acceleration of Memset Pattern

## 35.5 Functional Description

### 35.5.1 Basic Definitions

**Source Peripheral:** Client device, memory mapped on the interconnection network, from where the XDMAC reads data. The source peripheral teams up with a destination peripheral to form a channel. A data read operation is scheduled when the peripheral transfer request is asserted.

**Destination Peripheral:** Client device, memory mapped on the interconnection network, to which the XDMAC writes. A write data operation is scheduled when the peripheral transfer request is asserted.

**Channel:** The data movement between source and destination creates a logical channel.

**Transfer Type:** The transfer is hardware-synchronized when it is paced by the peripheral hardware request, otherwise the transfer is self-triggered (memory to memory transfer).

### 35.5.2 Transfer Hierarchy Diagram

**XDMAC Host Transfer:** The Host Transfer is composed of a linked list of blocks. The channel address, control and configuration registers can be modified at the inter block boundary. The descriptor structure modifies the channel registers conditionally. Interrupts can be generated on a per block basis or when the end of linked list event occurs.

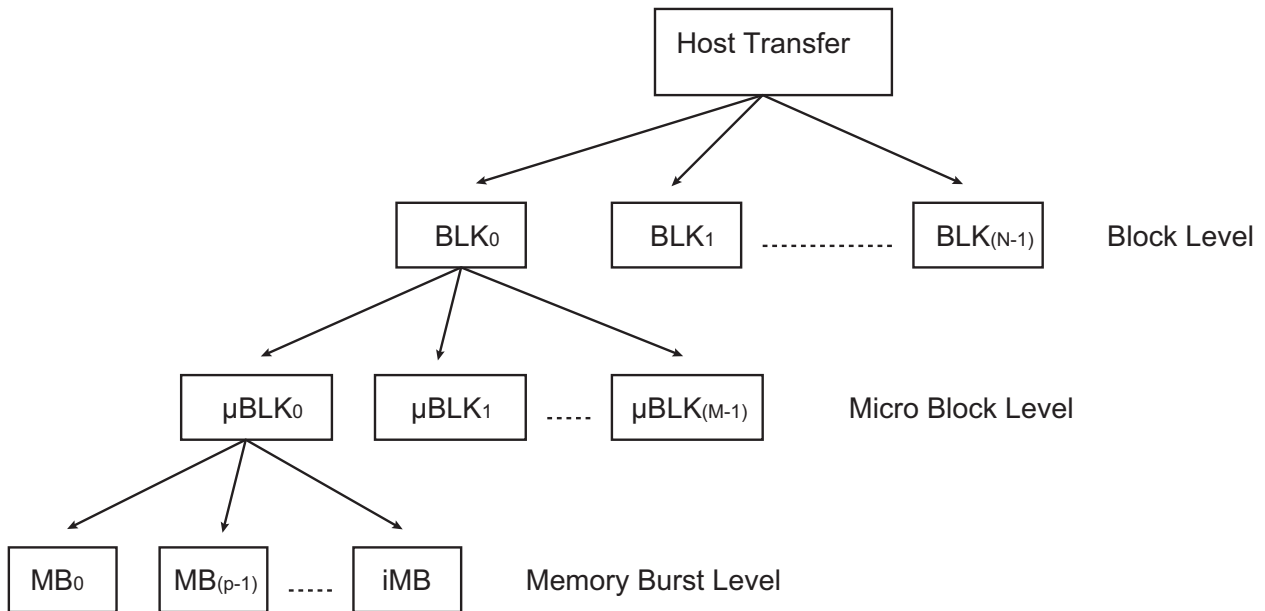

**XDMAC Block:** An XDMAC block is composed of a programmable number of microblocks. The channel configuration registers remain unchanged at the inter microblock boundary. The source and destination addresses are conditionally updated with a programmable signed number.

**XDMAC Microblock:** The microblock is composed of a programmable number of data. The channel configuration registers remain unchanged at the data boundary. The data address may be fixed (a FIFO location, a peripheral transmit or receive register), incrementing (a memory-mapped area) by a programmable signed number.

**XDMAC Burst and Incomplete Burst:** In order to improve the overall performance when accessing dynamic external memory, burst access is mandatory. Each data of the microblock is considered as a part of a memory burst. The programmable burst value indicates the largest memory burst allowed on a per channel basis. When the microblock length is not an integral multiple of the burst size, an incomplete burst is performed to read or write the last trailing bytes.

**XDMAC Chunk and Incomplete Chunk:** When a peripheral synchronized transfer is activated, the microblock splits into a number of data chunks. The chunk size is programmable. The larger the chunk is, the better the performance is. When the transfer size is not a multiple of the chunk size, the last chunk may be incomplete.

**Figure 35-2. XDMAC Memory Transfer Hierarchy**

**Figure 35-3. XDMAC Peripheral Transfer Hierarchy**

### 35.5.3 Peripheral Synchronized Transfer

A peripheral hardware request interface is used to control the pace of the chunk transfer. When a peripheral is ready to transmit or receive a chunk of data, it asserts its request line and the DMA Controller transfers a data to or from the memory to the peripheral.

#### 35.5.3.1 Software Triggered Synchronized Transfer

The Peripheral hardware request can be software controlled using the SWREQ field of the XDMAC Global Channel Software Request Register (XDMAC\_GSWR). The peripheral synchronized transfer is paced using a processor write access in the XDMAC\_GSWR. Each bit of that register triggers a transfer request. The XDMAC Global Channel Software Request Status Register (XDMAC\_GSWS) indicates the status of the request; when set, the request is still pending.

### 35.5.4 XDMAC Transfer Software Operation

#### 35.5.4.1 Single Block Transfer With Single Microblock

1. Read the XDMAC Global Channel Status Register (XDMAC\_GS) to select a free channel.
2. Clear the pending Interrupt Status bit(s) by reading the selected XDMAC Channel x Interrupt Status Register (XDMAC\_CISx).
3. Write the XDMAC Channel x Source Address Register (XDMAC\_CSAx) for channel x.
4. Write the XDMAC Channel x Destination Address Register (XDMAC\_CDAx) for channel x.
5. Program field UBLEN in the XDMAC Channel x Microblock Control Register (XDMAC\_CUBCx) with the number of data.
6. Program the XDMAC Channel x Configuration Register (XDMAC\_CCx):
  - a. Clear XDMAC\_CCx.TYPE for a memory-to-memory transfer, otherwise set this bit.
  - b. Configure XDMAC\_CCx.MBSIZE to the memory burst size used.
  - c. Configure XDMAC\_CCx.SAM and DAM to Memory Addressing mode.
  - d. Configure XDMAC\_CCx.DSYNC to select the peripheral transfer direction.
  - e. Configure XDMAC\_CCx.CSIZE to configure the channel chunk size (only relevant for peripheral synchronized transfer).
  - f. Configure XDMAC\_CCx.DWIDTH to configure the transfer data width.
  - g. Configure XDMAC\_CCx.SIF, XDMAC\_CCx.DIF to configure the Host interface used to read data and write data, respectively.
  - h. Configure XDMAC\_CCx.PERID to select the active hardware request line (only relevant for a peripheral synchronized transfer).
  - i. Set XDMAC\_CCx.SWREQ to use a software request (only relevant for a peripheral synchronized transfer).
7. Clear the following five registers:
  - XDMAC Channel x Next Descriptor Control Register (XDMAC\_CNDCx)
  - XDMAC Channel x Block Control Register (XDMAC\_CBCx)
  - XDMAC Channel x Data Stride Memory Set Pattern Register (XDMAC\_CDS\_MSPx)
  - XDMAC Channel x Source Microblock Stride Register (XDMAC\_CSUSx)
  - XDMAC Channel x Destination Microblock Stride Register (XDMAC\_CDUSx)This indicates that the linked list is disabled, there is only one block and striding is disabled.
8. Enable the Microblock interrupt by writing a '1' to bit BIE in the XDMAC Channel x Interrupt Enable Register (XDMAC\_CIEx). Enable the Channel x Interrupt Enable bit by writing a '1' to bit IEx in the XDMAC Global Interrupt Enable Register (XDMAC\_GIE).
9. Enable channel x by writing a '1' to bit ENx in the XDMAC Global Channel Enable Register (XDMAC\_GE). XDMAC\_GS.STx (XDMAC Channel x Status bit) is set by hardware.
10. Once completed, the DMA channel sets XDMAC\_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC\_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

#### 35.5.4.2 Single Block Transfer With Multiple Microblock

1. Read the XDMAC\_GS register to choose a free channel.
2. Clear the pending Interrupt Status bit by reading the chosen XDMAC\_CISx register.
3. Write the XDMAC\_CSAx register for channel x.
4. Write the XDMAC\_CDAx register for channel x.
5. Program XDMAC\_CUBCx.UBLEN with the number of data.
6. Program XDMAC\_CCx register (see [“Single Block Transfer With Single Microblock”](#)).
7. Program XDMAC\_CBCx.BLEN with the number of microblocks of data.
8. Clear the following registers:
  - XDMAC\_CNDCx
  - XDMAC\_CDS\_MSPx
  - XDMAC\_CSUSx XDMAC\_CDUSx

This indicates that the linked list is disabled and striding is disabled.

9. Enable the Block interrupt by writing a '1' to XDMAC\_CIEx.BIE, enable the Channel x Interrupt Enable bit by writing a '1' to XDMAC\_GIEx.IEx.
10. Enable channel x by writing a '1' to the XDMAC\_GE.ENx. XDMAC\_GS.STx is set by hardware.
11. Once completed, the DMA channel sets XDMAC\_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC\_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

### 35.5.4.3 Host Transfer

1. Read the XDMAC\_GS register to choose a free channel.
2. Clear the pending Interrupt Status bit by reading the chosen XDMAC\_CISx register.
3. Build a linked list of transfer descriptors in memory. The descriptor view is programmable on a per descriptor basis. The linked list items structure must be word aligned. MBR\_UBC.NDE must be configured to 0 in the last descriptor to terminate the list.
4. Configure field NDA in the XDMAC Channel x Next Descriptor Address Register (XDMAC\_CNDAx) with the first descriptor address and bit XDMAC\_CNDAx.NDAIF with the Host interface identifier.
5. Configure the XDMAC\_CNDCx register:
  - a. Set XDMAC\_CNDCx.NDE to enable the descriptor fetch.
  - b. Set XDMAC\_CNDCx.NDSUP to update the source address at the descriptor fetch time, otherwise clear this bit.
  - c. Set XDMAC\_CNDCx.NDDUP to update the destination address at the descriptor fetch time, otherwise clear this bit.
  - d. Configure XDMAC\_CNDCx.NDVIEW to define the length of the first descriptor.
6. Enable the End of Linked List interrupt by writing a '1' to XDMAC\_CIEx.LIE.
7. Enable channel x by writing a '1' to XDMAC\_GE.ENx. XDMAC\_GS.STx is set by hardware.
8. Once completed, the DMA channel sets XDMAC\_CISx.BIS (End of Block Interrupt Status bit) and generates an interrupt. XDMAC\_GS.STx is cleared by hardware. The software can either wait for an interrupt or poll the channel status bit.

### 35.5.4.4 Disabling A Channel Before Transfer Completion

Under normal operation, the software enables a channel by writing a '1' to XDMAC\_GE.ENx, then the hardware disables a channel on transfer completion by clearing bit XDMAC\_GS.STx. To disable a channel, write a '1' to bit XDMAC\_GD.DIx and poll the XDMAC\_GS register.

## 35.6 Linked List Descriptor Operation

### 35.6.1 Linked List Descriptor View

**Table 35-2. Channel Next Descriptor View 0–3 Structures**

| Channel Next Descriptor | Offset         | Structure member               | Name    |
|-------------------------|----------------|--------------------------------|---------|
| View 0 Structure        | DSCR_ADDR+0x00 | Next Descriptor Address Member | MBR_NDA |
|                         | DSCR_ADDR+0x04 | Microblock Control Member      | MBR_UBC |

### 35.6.2 Descriptor Structure Members Description

#### 35.6.2.1 View 0 Descriptor

|  |
|--|
| Next Descriptor Address Member (MBR_NDA) |
| Microblock Control Member (MBR_UBC)      |
| Transfer Address Member (MBR_TA)         |

View0 is the simplest descriptor having just three members.

#### **Next Descriptor Address Member (MBR\_NDA):**

MBR\_NDA is similar to XDMAC Channel Next Descriptor register (XDMAC\_CNDAx). The XDMAC\_CNDAx register is initialized to the address of the first descriptor of the linked list, whereas Next Descriptor Address Member (MBR\_NDA) is initialized to the address of the subsequent descriptor to be fetched from the linked list. If there are no further descriptors present in the linked list, then MBR\_NDA should be initialized with 0. When a descriptor is fetched, XDMAC\_CNDAx register is updated with MBR\_NDA value for the execution of the next descriptor (Block).

#### **TransferAddress Member (MBR\_TA):**

Transfer Address Member (MBR\_TA) should be written with the destination address during Memory-to-Memory and Peripheral-to-Memory transfers. When the descriptor is fetched, the Channel Destination Address register (XDMAC\_CDAx) is updated with the valued stored in Transfer Address member (MBR\_TA) based on the previous descriptor's MBR\_UBC.NDEN value.

Transfer Address Member (MBR\_TA) should be written with the source address during Memory-to-Peripheral transfer. When the descriptor is fetched, the Channel Source Address register (XDMAC\_CSAx) is updated with the values stored in Transfer Address member (MBR\_TA) based on the previous descriptor's MBR\_UBC.NSEN value.

**Note:** For the first descriptor of the linked list, XDMAC\_CNDCx.NDSUP and XDMAC\_CNDCx.NDDUP values should be directly initialized. These values decide whether to update the Channel Source/Destination Address registers with MBR\_TA or not.

### 35.6.2.2 View 1 Descriptor

|  |
|--|
| Next Descriptor Address Member (MBR_NDA) |
| Microblock Control Member (MBR_UBC)      |
| Source Address Member (MBR_SA)           |
| Destination Address Member (MBR_DA)      |

View 1 descriptor has two extra members in addition to View 0 descriptor.

#### **Source Address Member (MBR\_SA):**

It contains the source address value of the corresponding descriptor (BLOCK). The value of MBR\_SA is copied to the Channel Source Address register (XDMAC\_CSAX) based on the previous MBR\_UBC.NSEN settings. Therefore, the source address can be changed between different descriptors (BLOCKS).

**Note:** For the first descriptor of the linked list, the XDMAC\_CNDCx.NDSUP value should be directly initialized. This value decides whether to update Channel Source Address register (XDMAC\_CSAX) with MBR\_SA or not.

#### **Destination Address Member (MBR\_DA):**

It contains the destination address value of the corresponding descriptor (BLOCK). The value of MBR\_DA is copied to the Channel Destination Address register (XDMAC\_CDAx) based on the previous MBR\_UBC.NDEN settings. Therefore, the destination address can be changed between different descriptors (BLOCKS).

**Note:** For the first descriptor of the linked list, the XDMAC\_CNDCx.NDDUP value should be directly initialized. This value decides whether to update Channel Destination Address register (XDMAC\_CDAx) with MBR\_DA or not.

### 35.6.2.3 View 2 Descriptor

|  |
|--|
| Next Descriptor Address Member (MBR_NDA) |
| Microblock Control Member (MBR_UBC)      |
| Source Address Member (MBR_SA)           |
| Destination Address Member (MBR_DA)      |
| Configuration Member (MBR_CFG)           |

View2 descriptor has Configuration Member (MBR\_CFG) in addition to View 1 descriptor.

#### **ConfigurationMember (MBR\_CFG):**

MBR\_CFG is similar to the XDMAC\_CCx register. During the descriptor fetch, the value of MBR\_CFG is copied to the XDMAC\_CCx register.

### 35.6.2.4 View 3 Descriptor

|  |
|--|
| Next Descriptor Address Member (MBR_NDA)       |
| Microblock Control Member (MBR_UBC)            |
| Source Address Member (MBR_SA)                 |
| Destination Address Member (MBR_DA)            |
| Configuration Member (MBR_CFG)                 |
| Block Control Member (MBR_BC)                  |
| Data Stride Member (MBR_DS)                    |
| Source Microblock Stride Member (MBR_SUS)      |
| Destination Microblock Stride Member (MBR_DUS) |

View3 descriptor has four extra members in addition to View 2 descriptor.

**Block Control Member (MBR\_BC):**

MBR\_BC is similar to the Channel Block Control Register (XDMAC\_CBCx). During the descriptor fetch, the value of MBR\_BC is copied to the XDMAC\_CBCx register.

**Data Stride Member (MBR\_DS):**

MBR\_DS is similar to the Channel Data Stride Memory Set Pattern Register (XDMAC\_CDS\_MSPx). During the descriptor fetch, the value of MBR\_DS is copied to the XDMAC\_CDS\_MSPx register.

**Source Microblock Stride Member (MBR\_SUS):**

MBR\_SUS is similar to the Channel Source Microblock Stride Register (XDMAC\_CSUSx). During the descriptor fetch, the value of MBR\_SUS is copied to the XDMAC\_CSUSx register.

**Destination Microblock Stride Member (MBR\_DUS):**

MBR\_DUS is similar to the Channel Destination Microblock Stride Register (XDMAC\_CDUSx). During the descriptor fetch, the value of MBR\_DUS is copied to the XDMAC\_CDUSx register.

### 35.6.2.5 Descriptor Structure Microblock Control Member

**Name:** MBR\_UBC  
**Property:** Read-only

|        |     |              |    |    |            |    |      |      |     |
|--------|-----|--------------|----|----|------------|----|------|------|-----|
|        | Bit | 31           | 30 | 29 | 28         | 27 | 26   | 25   | 24  |

| Reset  |     |              |    |    |            |    |      |      |     |
|        |     |              |    |    |            |    |      |      |     |
|        | Bit | 23           | 22 | 21 | 20         | 19 | 18   | 17   | 16  |
|        |     | UBLEN[23:16] |    |    |            |    |      |      |     |
| Access |     | R            | R  | R  | R          | R  | R    | R    | R   |
| Reset  |     |              |    |    |            |    |      |      |     |
|        |     |              |    |    |            |    |      |      |     |
|        | Bit | 15           | 14 | 13 | 12         | 11 | 10   | 9    | 8   |
|        |     | UBLEN[15:8]  |    |    |            |    |      |      |     |
| Access |     | R            | R  | R  | R          | R  | R    | R    | R   |
| Reset  |     |              |    |    |            |    |      |      |     |
|        |     |              |    |    |            |    |      |      |     |
|        | Bit | 7            | 6  | 5  | 4          | 3  | 2    | 1    | 0   |
|        |     | UBLEN[7:0]   |    |    |            |    |      |      |     |
| Access |     | R            | R  | R  | R          | R  | R    | R    | R   |
| Reset  |     |              |    |    |            |    |      |      |     |

#### Bits 28:27 – NVIEW[1:0] Next Descriptor View

| Value | Name | Description            |
|-------|------|------------------------|
| 0     | NDV0 | Next Descriptor View 0 |
| 1     | NDV1 | Next Descriptor View 1 |
| 2     | NDV2 | Next Descriptor View 2 |
| 3     | NDV3 | Next Descriptor View 3 |

#### Bit 26 – NDEN Next Descriptor Destination Update

| Value | Description  |
|-------|--|
| 0     | Destination parameters remain unchanged.                             |
| 1     | Destination parameters are updated when the descriptor is retrieved. |

#### Bit 25 – NSEN Next Descriptor Source Update

| Value | Description   |
|-------|---|
| 0     | Source parameters remain unchanged.                             |
| 1     | Source parameters are updated when the descriptor is retrieved. |

#### Bit 24 – NDE Next Descriptor Enable

| Value | Description                   |
|-------|-------------------------------|
| 0     | Descriptor fetch is disabled. |
| 1     | Descriptor fetch is enabled.  |

#### Bits 23:0 – UBLEN[23:0] Microblock Length

This field indicates the number of data in the microblock. The microblock contains UBLEN data.

## **35.7 XDMAC Maintenance Software Operations**

### **35.7.1 Disabling a Channel**

A disable channel request occurs when a write operation is performed in the XDMAC\_GD register. If the channel is source peripheral synchronized (bit XDMAC\_CCx.TYPE is set and bit XDMAC\_CCx.DSYNC is cleared), then pending bytes (bytes located in the FIFO) are written to memory and bit XDMAC\_CISx.DIS is set. If the channel is not source peripheral synchronized, the current channel transaction (read or write) is terminated and XDMAC\_CISx.DIS is set. XDMAC\_GS.STx is cleared by hardware when the current transfer is completed. The channel is no longer active and can be reused.

### **35.7.2 Suspending a Channel**

A read request suspend command is issued by writing to the XDMAC\_GRS register. A write request suspend command is issued by writing to the XDMAC\_GWS register. A read write suspend channel is issued by writing to the XDMAC\_GRWS register. These commands have an immediate effect on the scheduling of both read and write transactions. If a transaction is already in progress, it is terminated normally. The channel is not disabled. The FIFO content is preserved. The scheduling can resume normally, clearing the bit in the same registers. Pending bytes located in the FIFO are not written out to memory. The write suspend command does not affect read request operations, that is, read operations can still occur until the FIFO is full.

### **35.7.3 Flushing a Channel**

A FIFO flush command is issued by writing to the XDMAC\_SWF register. The content of the FIFO is written to memory. XDMAC\_CISx.FIS (End of Flush Interrupt Status bit) is set when the last byte is successfully transferred to memory. The channel is not disabled. The flush operation is not blocking, meaning that read operation can be scheduled during the flush write operation. The flush operation is only relevant for peripheral to memory transfer where pending peripheral bytes are buffered into the channel FIFO.

### **35.7.4 Maintenance Operation Priority**

#### **35.7.4.1 Disable Operation Priority**

- When a disable request occurs on a suspended channel, the XDMAC\_GWS.WSx (Channel x Write Suspend bit) is cleared. If the transfer is source peripheral synchronized, the pending bytes are drained to memory. The bit XDMAC\_CISx.DIS is set.
- When a disable request follows a flush request, if the flush last transaction is not yet scheduled, the flush request is discarded and the disable procedure is applied. Bit XDMAC\_CISx.FIS is not set. Bit XDMAC\_CISx.DIS is set when the disable request is completed. If the flush request transaction is already scheduled, the XDMAC\_CISx.FIS is set. XDMAC\_CISx.DIS is also set when the disable request is completed.

#### **35.7.4.2 Flush Operation Priority**

- When a flush request occurs on a suspended channel, if there are pending bytes in the FIFO, they are written out to memory, XDMAC\_CISx.FIS is set. If the FIFO is empty, XDMAC\_CISx.FIS is also set.
- If the flush operation is performed after a disable request, the flush command is ignored. XDMAC\_CISx.FIS is not set.

#### **35.7.4.3 Suspend Operation Priority**

If the suspend operation is performed after a disable request, the write suspend operation is ignored.

## **35.8 XDMAC Software Requirements**

- Write operations to channel registers are not be performed in an active channel after the channel is enabled. If any channel parameters must be reprogrammed, this can only be done after disabling the XDMAC channel.
- XDMAC\_CSx and XDMAC\_CDx channel registers are to be programmed with a byte, half-word or word aligned address depending on the Channel x Data Width field (DWIDTH) of the XDMAC Channel x Configuration Register.

- When XDMAC\_CC.INITD is set to 0, XDMAC\_CUBC.UBLEN and XDMAC\_CNDA.NDA field values are unreliable when the descriptor is being updated. The following procedure applies to get the buffer descriptor identifier and the residual bytes:

```

Read XDMAC_CNDAx.NDA(nda0)
Read XDMAC_CCx.INITD(initd0)
Read XDMAC_CCx.INITD(initd1)
Read XDMAC_CUBCx.UBLEN(ublen)
Read XDMAC_CCx.INITD(initd1)
Read XDMA_CNDAx.NDA(nda1)
If (nda0 == nda1 && initd0 == 1 && initd1 == 1).
Then the ublen is correct, the buffer id is nda.
Else retry
    
```

See the figure below.

# SAM E70/S70/V70/V71

## DMA Controller (XDMAC)

### 35.9 Register Summary

| Offset | Name        | Bit Pos. | 7             | 6    | 5    | 4          | 3       | 2         | 1         | 0        |  |
|--------|-------------|----------|---------------|------|------|------------|---------|-----------|-----------|----------|--|
| 0x00   | XDMAC_GTYPE | 7:0      | FIFO_SZ[2:0]  |      |      | NB_CH[4:0] |         |           |           |          |  |
|        |             | 15:8     | FIFO_SZ[10:3] |      |      |            |         |           |           |          |  |
|        |             | 23:16    | NB_REQ[6:0]   |      |      |            |         |           |           |          |  |
|        |             | 31:24    |               |      |      |            |         |           |           |          |  |
| 0x04   | XDMAC_GCFG  | 7:0      |               |      |      |            | CGDISIF | CGDISFIFO | CGDISPIPE | CGDISREG |  |
|        |             | 15:8     |               |      |      |            |         |           |           | BXKBEN   |  |
|        |             | 23:16    |               |      |      |            |         |           |           |          |  |
|        |             | 31:24    |               |      |      |            |         |           |           |          |  |
| 0x08   | XDMAC_GWAC  | 7:0      | PW1[3:0]      |      |      | PW0[3:0]   |         |           |           |          |  |
|        |             | 15:8     | PW3[3:0]      |      |      | PW2[3:0]   |         |           |           |          |  |
|        |             | 23:16    |               |      |      |            |         |           |           |          |  |
|        |             | 31:24    |               |      |      |            |         |           |           |          |  |
| 0x0C   | XDMAC_GIE   | 7:0      |               | IE6  | IE5  | IE4        | IE3     | IE2       | IE1       | IE0      |  |
|        |             | 15:8     |               |      |      |            |         |           |           |          |  |

| Access |     | R             | R  | R  | R          | R  | R  | R  | R  |
| Reset  |     | 0             | 0  | 0  | 0          | 0  | 0  | 0  | 0  |

**Bits 22:16 – NB\_REQ[6:0]** Number of Peripheral Requests Minus One

**Bits 15:5 – FIFO\_SZ[10:0]** Number of Bytes

**Bits 4:0 – NB\_CH[4:0]** Number of Channels Minus One

### 35.9.2 XDMAC Global Configuration Register

**Name:** XDMAC\_GCFCG  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 8 – BXKBEN** Boundary X Kilobyte Enable

| Value | Description   |
|-------|---|
| 0     | The 1 Kbyte boundary is used.                       |
| 1     | The controller does not meet the AHB specification. |

**Bit 3 – CGDISIF** Bus Interface Clock Gating Disable

| Value | Description  |
|-------|--|
| 0     | The automatic clock gating is enabled for the system bus interface.  |
| 1     | The automatic clock gating is disabled for the system bus interface. |

**Bit 2 – CGDISFIFO** FIFO Clock Gating Disable

| Value | Description   |
|-------|---|
| 0     | The automatic clock gating is enabled for the main FIFO.  |
| 1     | The automatic clock gating is disabled for the main FIFO. |

**Bit 1 – CGDISPIPE** Pipeline Clock Gating Disable

| Value | Description   |
|-------|---|
| 0     | The automatic clock gating is enabled for the main pipeline.  |
| 1     | The automatic clock gating is disabled for the main pipeline. |

**Bit 0 – CGDISREG** Configuration Registers Clock Gating Disable

| Value | Description   |
|-------|---|
| 0     | The automatic clock gating is enabled for the configuration registers.  |
| 1     | The automatic clock gating is disabled for the configuration registers. |

### 35.9.3 XDMAC Global Weighted Arbiter Configuration Register

**Name:** XDMAC\_GWAC  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 15:12 – PW3[3:0]** Pool Weight 3  
 This field indicates the weight of pool 3 in the arbitration scheme of the DMA scheduler.

**Bits 11:8 – PW2[3:0]** Pool Weight 2  
 This field indicates the weight of pool 2 in the arbitration scheme of the DMA scheduler.

**Bits 7:4 – PW1[3:0]** Pool Weight 1  
 This field indicates the weight of pool 1 in the arbitration scheme of the DMA scheduler.

**Bits 3:0 – PW0[3:0]** Pool Weight 0  
 This field indicates the weight of pool 0 in the arbitration scheme of the DMA scheduler.

### 35.9.4 XDMAC Global Interrupt Enable Register

**Name:** XDMAC\_GIE  
**Offset:** 0x0C  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – IE XDMAC Channel x Interrupt Enable**

| Value | Description   |
|-------|---|
| 0     | This bit has no effect. The Channel x Interrupt Mask bit (XDMAC_GIM.IMx) is not modified.                               |
| 1     | The corresponding mask bit is set. The XDMAC Channel x Interrupt Status register (XDMAC_GIS) can generate an interrupt. |

### 35.9.5 XDMAC Global Interrupt Disable Register

**Name:** XDMAC\_GID  
**Offset:** 0x10  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – ID XDMAC Channel x Interrupt Disable**

| Value | Description   |
|-------|---|
| 0     | This bit has no effect. The Channel x Interrupt Mask bit (XDMAC_GIM.IMx) is not modified.                     |
| 1     | The corresponding mask bit is reset. The Channel x Interrupt Status register interrupt (XDMAC_GIS) is masked. |

**35.9.6 XDMAC Global Interrupt Mask Register**

**Name:** XDMAC\_GIM  
**Offset:** 0x14  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 0, 1, 2, 3, 4, 5, 6 – IM XDMAC Channel x Interrupt Mask**

| Value | Description   |
|-------|---|
| 0     | This bit indicates that the channel x interrupt source is masked. The interrupt line is not raised. |
| 1     | This bit indicates that the channel x interrupt source is unmasked.                                 |

### 35.9.7 XDMAC Global Interrupt Status Register

**Name:** XDMAC\_GIS  
**Offset:** 0x18  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 0, 1, 2, 3, 4, 5, 6 – IS XDMAC Channel x Interrupt Status**

| Value | Description  |
|-------|--|
| 0     | This bit indicates that either the interrupt source is masked at the channel level or no interrupt is pending for channel x. |
| 1     | This bit indicates that an interrupt is pending for the channel x.   |

### 35.9.8 XDMAC Global Channel Enable Register

**Name:** XDMAC\_GE  
**Offset:** 0x1C  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – EN** XDMAC Channel x Enable

| Value | Description  |
|-------|--|
| 0     | This bit has no effect.  |
| 1     | Enables channel n. This operation is permitted if the Channel x Status bit (XDMAC_GS.STx) was read as '0'. |

**35.9.9 XDMAC Global Channel Disable Register**

**Name:** XDMAC\_GD  
**Offset:** 0x20  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – DI XDMAC Channel x Disable**

| Value | Description             |
|-------|-------------------------|
| 0     | This bit has no effect. |
| 1     | Disables channel x.     |

**35.9.10 XDMAC Global Channel Status Register**

**Name:** XDMAC\_GS  
**Offset:** 0x24  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 0, 1, 2, 3, 4, 5, 6 – ST XDMAC Channel x Status**

| Value | Description   |
|-------|---|
| 0     | This bit indicates that the channel x is disabled.  |
| 1     | This bit indicates that the channel x is enabled. If a channel disable request is issued, this bit remains asserted until pending transaction is completed. |

**35.9.11 XDMAC Global Channel Read Suspend Register**

**Name:** XDMAC\_GRS  
**Offset:** 0x28  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 0, 1, 2, 3, 4, 5, 6 – RSx** XDMAC Channel x Read Suspend

| Value | Description   |
|-------|---|
| 0     | The read channel is not suspended.  |
| 1     | The source requests for channel n are no longer serviced by the system scheduler. |

**35.9.12 XDMAC Global Channel Write Suspend Register**

**Name:** XDMAC\_GWS  
**Offset:** 0x2C  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 0, 1, 2, 3, 4, 5, 6 – WSx** XDMAC Channel x Write Suspend

| Value | Description   |
|-------|---|
| 0     | The write channel is not suspended.                         |
| 1     | Destination requests are no longer routed to the scheduler. |

### 35.9.13 XDMAC Global Channel Read Write Suspend Register

**Name:** XDMAC\_GRWS  
**Offset:** 0x30  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – RWSx** XDMAC Channel x Read Write Suspend

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Read and write requests are suspended. |

**35.9.14 XDMAC Global Channel Read Write Resume Register**

**Name:** XDMAC\_GRWR  
**Offset:** 0x34  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – RWRx** XDMAC Channel x Read Write Resume

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Read and write requests are serviced. |

**35.9.15 XDMAC Global Channel Software Request Register**

**Name:** XDMAC\_GSWR  
**Offset:** 0x38  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – SWREQ** XDMAC Channel x Software Request

| Value | Description                            |
|-------|--|
| 0     | No effect.                             |
| 1     | Requests a DMA transfer for channel x. |

**35.9.16 XDMAC Global Channel Software Request Status Register**

**Name:** XDMAC\_GSWS  
**Offset:** 0x3C  
**Reset:** 0x00000000  
**Property:** Read-only

|        |     |                      |       |       |       |       |       |       |       |
|--------|-----|----------------------|-------|-------|-------|-------|-------|-------|-------|
|        | Bit | 31                   | 30    | 29    | 28    | 27    | 26    | 25    | 24    |
|        |     | [Register Bit Field] |       |       |       |       |       |       |       |
| Access |     |                      |       |       |       |       |       |       |       |
| Reset  |     |                      |       |       |       |       |       |       |       |
|        |     |                      |       |       |       |       |       |       |       |
|        | Bit | 23                   | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
|        |     | [Register Bit Field] |       |       |       |       |       |       |       |
| Access |     |                      |       |       |       |       |       |       |       |

|        |     |                      | SWRS6 | SWRS5 | SWRS4 | SWRS3 | SWRS2 | SWRS1 | SWRS0 |
| Access |     |                      | R     | R     | R     | R     | R     | R     | R     |
| Reset  |     |                      | 0     | 0     | 0     | 0     | 0     | 0     | 0     |

**Bits 0, 1, 2, 3, 4, 5, 6 – SWRS** XDMAC Channel x Software Request Status

| Value | Description                           |
|-------|---------------------------------------|
| 0     | Channel x source request is serviced. |
| 1     | Channel x source request is pending.  |

### 35.9.17 XDMAC Global Channel Software Flush Request Register

**Name:** XDMAC\_GSWF  
**Offset:** 0x40  
**Reset:** –  
**Property:** Write-only

**Bits 0, 1, 2, 3, 4, 5, 6 – SWF<sub>x</sub>** XDMAC Channel x Software Flush Request

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Requests a DMA transfer flush for channel x. This bit is only relevant when the transfer is source peripheral synchronized. |

### 35.9.18 XDMAC Channel x Interrupt Enable Register [x=0..6]

**Name:** XDMAC\_CIE  
**Offset:** 0x50 + n\*0x40 [n=0..6]  
**Reset:** –  
**Property:** Write-only

|        |     |    |      |      |      |     |     |     |     |

| Reset  |     |    | –    | –    | –    | –   | –   | –   | –   |

#### Bit 6 – ROIE Request Overflow Error Interrupt Enable Bit

| Value | Description                               |
|-------|---|
| 0     | No effect.                                |
| 1     | Enables request overflow error interrupt. |

#### Bit 5 – WBIE Write Bus Error Interrupt Enable Bit

| Value | Description                        |
|-------|------------------------------------|
| 0     | No effect.                         |
| 1     | Enables write bus error interrupt. |

#### Bit 4 – RBIE Read Bus Error Interrupt Enable Bit

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Enables read bus error interrupt. |

#### Bit 3 – FIE End of Flush Interrupt Enable Bit

| Value | Description                     |
|-------|---------------------------------|
| 0     | No effect.                      |
| 1     | Enables end of flush interrupt. |

#### Bit 2 – DIE End of Disable Interrupt Enable Bit

| Value | Description                       |
|-------|-----------------------------------|
| 0     | No effect.                        |
| 1     | Enables end of disable interrupt. |

#### Bit 1 – LIE End of Linked List Interrupt Enable Bit

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Enables end of linked list interrupt. |

**SAM E70/S70/V70/V71**  
**DMA Controller (XDMAC)**

**Bit 0 – BIE** End of Block Interrupt Enable Bit

| <b>Value</b> | <b>Description</b>              |
|--------------|---------------------------------|
| 0            | No effect.                      |
| 1            | Enables end of block interrupt. |

### 35.9.19 XDMAC Channel x Interrupt Disable Register [x = 0..6]

**Name:** XDMAC\_CID  
**Offset:** 0x54 + n\*0x40 [n=0..6]  
**Reset:** –

#### Bit 6 – ROIS Request Overflow Error Interrupt Status Bit

| Value | Description   |
|-------|---|
| 0     | Overflow condition has not occurred.  |
| 1     | Overflow condition has occurred at least once. (This information is only relevant for peripheral synchronized transfers.) |

#### Bit 5 – WBEIS Write Bus Error Interrupt Status Bit

| Value | Description  |
|-------|--|
| 0     | Write bus error condition has not occurred.  |
| 1     | At least one bus error has been detected in a write access since the last read of the Status register. |

#### Bit 4 – RBEIS Read Bus Error Interrupt Status Bit

| Value | Description   |
|-------|---|
| 0     | Read bus error condition has not occurred.  |
| 1     | At least one bus error has been detected in a read access since the last read of the Status register. |

#### Bit 3 – FIS End of Flush Interrupt Status Bit

| Value | Description   |
|-------|---|
| 0     | End of flush condition has not occurred.  |
| 1     | End of flush condition has occurred since the last read of the Status register. |

#### Bit 2 – DIS End of Disable Interrupt Status Bit

| Value | Description   |
|-------|---|
| 0     | End of disable condition has not occurred.  |
| 1     | End of disable condition has occurred since the last read of the Status register. |

#### Bit 1 – LIS End of Linked List Interrupt Status Bit

| Value | Description                                    |
|-------|--|
| 0     | End of linked list condition has not occurred. |

**SAM E70/S70/V70/V71**  
**DMA Controller (XDMAC)**

---

---

| Value | Description   |
|-------|---|
| 1     | End of linked list condition has occurred since the last read of the Status register. |

**Bit 0 – BIS** End of Block Interrupt Status Bit

| Value | Description   |
|-------|---|
| 0     | End of block interrupt has not occurred.  |
| 1     | End of block interrupt has occurred since the last read of the Status register. |

**Bits 31:2 – NDA[29:0]** Channel x Next Descriptor Address

The 30-bit width of the NDA field represents the next descriptor address range 31:2. The descriptor is word-aligned and the two least significant register bits 1:0 are ignored.

**Bit 0 – NDAIF** Channel x Next Descriptor Interface

| Value | Description   |
|-------|---|
| 0     | The channel descriptor is retrieved through system interface 0. |
| 1     | The channel descriptor is retrieved through system interface 1. |

### 35.9.25 XDMAC Channel x Next Descriptor Control Register [x = 0..6]

**Name:** XDMAC\_CNDC  
**Offset:** 0x6C + n\*0x40 [n=0..6]  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bits 4:3 – NDVIEW[1:0] Channel x Next Descriptor View

| Value | Name | Description            |
|-------|------|------------------------|
| 0     | NDV0 | Next Descriptor View 0 |
| 1     | NDV1 | Next Descriptor View 1 |
| 2     | NDV2 | Next Descriptor View 2 |
| 3     | NDV3 | Next Descriptor View 3 |

#### Bit 2 – NDDUP Channel x Next Descriptor Destination Update

- 0 (DST\_PARAMS\_UNCHANGED): Destination parameters remain unchanged.
- 1 (DST\_PARAMS\_UPDATED): Destination parameters are updated when the descriptor is retrieved.

#### Bit 1 – NDSUP Channel x Next Descriptor Source Update

- 0 (SRC\_PARAMS\_UNCHANGED): Source parameters remain unchanged.
- 1 (SRC\_PARAMS\_UPDATED): Source parameters are updated when the descriptor is retrieved.

#### Bit 0 – NDE Channel x Next Descriptor Enable

- 0 (DSCR\_FETCH\_DIS): Descriptor fetch is disabled.
- 1 (DSCR\_FETCH\_EN): Descriptor fetch is enabled.

**Bits 30:24 – PERID[6:0]** Channel x Peripheral Hardware Request Line Identifier

This field contains the peripheral hardware request line identifier. PERID refers to identifiers defined in [“DMA Controller Peripheral Connections”](#).

**Bit 23 – WRIP** Write in Progress (this bit is read-only)

0 (DONE): No active write transaction on the bus.  
 1 (IN\_PROGRESS): A write transaction is in progress.

**Bit 22 – RDIP** Read in Progress (this bit is read-only)

0 (DONE): No active read transaction on the bus.  
 1 (IN\_PROGRESS): A read transaction is in progress.

**Bit 21 – INITD** Channel Initialization Done (this bit is read-only)

0 (IN\_PROGRESS): Channel initialization is in progress.  
 1 (TERMINATED): Channel initialization is completed.  
 Note: When set to 0, XDMAC\_CUBC.UBLEN and XDMAC\_CNDA.NDA field values are unreliable each time a descriptor is being updated. See [35.8. XDMAC Software Requirements](#).

**Bits 19:18 – DAM[1:0]** Channel x Destination Addressing Mode

| Value | Name           | Description   |
|-------|----------------|---|
| 0     | FIXED_AM       | The address remains unchanged.  |
| 1     | INCREMENTED_AM | The addressing mode is incremented (the increment size is set to the data size).                          |
| 2     | UBS_AM         | The microblock stride is added at the microblock boundary.  |
| 3     | UBS_DS_AM      | The microblock stride is added at the microblock boundary; the data stride is added at the data boundary. |

**Bits 17:16 – SAM[1:0]** Channel x Source Addressing Mode

| Value | Name     | Description                    |
|-------|----------|--------------------------------|
| 0     | FIXED_AM | The address remains unchanged. |

# SAM E70/S70/V70/V71

## DMA Controller (XDMAC)

| Value | Name           | Description   |
|-------|----------------|---|
| 1     | INCREMENTED_AM | The addressing mode is incremented (the increment size is set to the data size).                          |
| 2     | UBS_AM         | The microblock stride is added at the microblock boundary.  |
| 3     | UBS_DS_AM      | The microblock stride is added at the microblock boundary, the data stride is added at the data boundary. |

**Bit 14 – DIF** Channel x Destination Interface Identifier  
 0 (AHB\_IF0): The data is written through system bus interface 0.  
 1 (AHB\_IF1): The data is written through system bus interface 1.

**Bit 13 – SIF** Channel x Source Interface Identifier  
 0 (AHB\_IF0): The data is read through system bus interface 0.  
 1 (AHB\_IF1): The data is read through system bus interface 1.

**Bits 12:11 – DWIDTH[1:0]** Channel x Data Width

| Value | Name     | Description                     |
|-------|----------|---------------------------------|
| 0     | BYTE     | The data size is set to 8 bits  |
| 1     | HALFWORD | The data size is set to 16 bits |
| 2     | WORD     | The data size is set to 32 bits |

**Bits 10:8 – CSIZE[2:0]** Channel x Chunk Size

| Value | Name   | Description         |
|-------|--------|---------------------|
| 0     | CHK_1  | 1 data transferred  |
| 1     | CHK_2  | 2 data transferred  |
| 2     | CHK_4  | 4 data transferred  |
| 3     | CHK_8  | 8 data transferred  |
| 4     | CHK_16 | 16 data transferred |

**Bit 7 – MEMSET** Channel x Fill Block of Memory  
 0 (NORMAL\_MODE): Memset is not activated.  
 1 (HW\_MODE): Sets the block of memory pointed by DA field to the specified value. This operation is performed on 8-, 16- or 32-bit basis.

**Bit 6 – SWREQ** Channel x Software Request Trigger  
 0 (HWR\_CONNECTED): Hardware request line is connected to the peripheral request line.  
 1 (SWR\_CONNECTED): Software request is connected to the peripheral request line.

**Bit 4 – DSYNC** Channel x Synchronization  
 0 (PER2MEM): Peripheral-to-memory transfer.  
 1 (MEM2PER): Memory-to-peripheral transfer.

**Bits 2:1 – MBSIZE[1:0]** Channel x Memory Burst Size

| Value | Name    | Description                              |
|-------|---------|--|
| 0     | SINGLE  | The memory burst size is set to one.     |
| 1     | FOUR    | The memory burst size is set to four.    |
| 2     | EIGHT   | The memory burst size is set to eight.   |
| 3     | SIXTEEN | The memory burst size is set to sixteen. |

**Bit 0 – TYPE** Channel x Transfer Type  
 0 (MEM\_TRAN): Self-triggered mode (memory-to-memory transfer).  
 1 (PER\_TRAN): Synchronized mode (peripheral-to-memory or memory-to-peripheral transfer).

### 35.9.29 XDMAC Channel x Data Stride Memory Set Pattern Register [x = 0..6]

 Two's complement microblock stride for channel x.

## 36. Image Sensor Interface

### 36.1 Description

The Image Sensor Interface (ISI) connects a CMOS-type image sensor to the processor and provides image capture in various formats. The ISI performs data conversion, if necessary, before the storage in memory through DMA.

The ISI supports color CMOS image sensor and grayscale image sensors with a reduced set of functionalities.

In Grayscale mode, the data stream is stored in memory without any processing, hence is not compatible with the LCD controller.

Internal FIFOs on the preview and codec paths are used to store the incoming data. The RGB output on the preview path is compatible with the LCD controller. This module outputs the data in RGB format (LCD compatible) and has scaling capabilities to make it compliant to the LCD display resolution, refer to the table [RGB Format in Default Mode, RGB\\_CFG = 00, No Swap](#).

Several input formats, such as preprocessed RGB or YCbCr are supported through the data bus interface.

The ISI supports two synchronization modes:

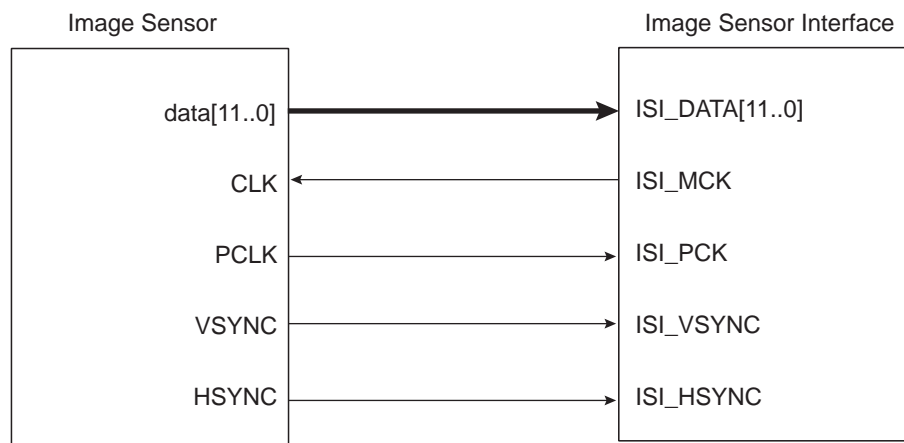

- Hardware with ISI\_VSYNC and ISI\_HSYNC signals
- International Telecommunication Union Recommendation ITU-R BT.656-4 Start-of-Active-Video (SAV) and End-of-Active-Video (EAV) synchronization sequence

Using EAV/SAV for synchronization reduces the pin count (ISI\_VSYNC, ISI\_HSYNC not used). The polarity of the synchronization pulse is programmable to comply with the sensor signals.

**Table 36-1. I/O Description**

| Signal          | Direction | Description   |
|-----------------|-----------|---|
| ISI_VSYNC       | In        | Vertical Synchronization                                    |

### 36.2 Embedded Characteristics

- ITU-R BT. 601/656 8-bit Mode External Interface Support
- Supports up to 12-bit Grayscale CMOS Sensors
- Support for ITU-R BT.656-4 SAV and EAV Synchronization
- Vertical and Horizontal Resolutions up to 2048 × 2048
- Preview Path up to 640 × 480 in RGB Mode
- Codec Path up to 2048 × 2048
- -byte FIFO on Codec Path
- -byte FIFO on Preview Path
- Support for Packed Data Formatting for YCbCr 4:2:2 Formats
- Preview Scaler to Generate Smaller Size image
- Programmable Frame Capture Rate
- VGA, QVGA, CIF, QCIF Formats Supported for LCD Preview
- Custom Formats with Horizontal and Vertical Preview Size as Multiples of 16 Also Supported for LCD Preview

### 36.3 Block Diagram

Figure 36-2. ISI Block Diagram

### 36.4 Product Dependencies

#### 36.4.1 I/O Lines

The pins used for interfacing the compliant external devices can be multiplexed with PIO lines. The programmer must first program the PIO controllers to assign the ISI pins to their peripheral functions.

#### 36.4.2 Power Management

The ISI can be clocked through the Power Management Controller (PMC), thus the programmer must first configure the PMC to enable the ISI clock.

#### 36.4.3 Interrupt Sources

The ISI interface has an interrupt line connected to the interrupt controller. Handling the ISI interrupt requires programming the interrupt controller before configuring the ISI.

## 36.5 Functional Description

The Image Sensor Interface (ISI) supports direct connection to the ITU-R BT. 601/656 8-bit mode compliant sensors and up to 12-bit grayscale sensors. It receives the image data stream from the image sensor on the 12-bit data bus.

This module receives up to 12 bits for data, the horizontal and vertical synchronizations and the pixel clock. The reduced pin count alternative for synchronization is supported for sensors that embed SAV (start of active video) and EAV (end of active video) delimiters in the data stream.

The Image Sensor Interface interrupt line is connected to the Advanced Interrupt Controller and can trigger an interrupt at the beginning of each frame and at the end of a DMA frame transfer. If the SAV/EAV synchronization is used, an interrupt can be triggered on each delimiter event.

For 8-bit color sensors, the data stream received can be in several possible formats: YCbCr 4:2:2, RGB 8:8:8, RGB 5:6:5 and may be processed before the storage in memory. When the preview DMA channel is configured and enabled, the preview path is activated and an 'RGB frame' is moved to memory. The preview path frame rate is configured with the FRATE field of the ISI\_CFG1 register. When the codec DMA channel is configured and enabled, the codec path is activated and a 'YCbCr 4:2:2 frame' is captured as soon as the ISI\_CDC bit of the ISI Control Register (ISI\_CR) is set.

When the FULL bit of the ISI\_CFG1 register is set, both preview DMA channel and codec DMA channel can operate simultaneously. When a zero is written to the FULL bit of the ISI\_CFG1 register, a hardware scheduler checks the FRATE field. If its value is zero, a preview frame is skipped and a codec frame is moved to memory instead. If its value is other than zero, at least one free frame slot is available. The scheduler postpones the codec frame to that free available frame slot.

The data stream may be sent on both preview path and codec path if the value of bit ISI\_CDC in the ISI\_CR is one. To optimize the bandwidth, the codec path should be enabled only when a capture is required.

In Grayscale mode, the input data stream is stored in memory without any processing. The 12-bit data, which represent the grayscale level for the pixel, is stored in memory one or two pixels per word, depending on the GS\_MODE bit in the ISI\_CFG2 register. The codec datapath is not available when grayscale image is selected.

A frame rate counter allows users to capture all frames or 1 out of every 2 to 8 frames.

### 36.5.1 Data Timing

#### 36.5.1.1 VSYNC/HSYNC Data Timing

In the VSYNC/HSYNC synchronization, the valid data is captured with the active edge of the pixel clock (ISI\_PCK), after SFD lines of vertical blanking and SLD pixel clock periods delay programmed in the ISI\_CR.

The data timing using horizontal and vertical synchronization are shown in the following figure.

**Figure 36-3. HSYNC and VSYNC Synchronization**

#### 36.5.1.2 SAV/EAV Data Timing

The ITU-RBT.656-4 standard defines the functional timing for an 8-bit wide interface.

There are two timing reference signals, one at the beginning of each video data block SAV (0xFF000080) and one at the end of each video data block EAV (0xFF00009D). Only data sent between EAV and SAV is captured. Horizontal blanking and vertical blanking are ignored. Use of the SAV and EAV synchronization eliminates the ISI\_VSYNC and ISI\_HSYNC signals from the interface, thereby reducing the pin count. In order to retrieve both frame and line synchronization properly, at least one line of vertical blanking is mandatory.

The data timing using EAV/SAV sequence synchronization are shown in the following figure.

**Figure 36-4. SAV and EAV Sequence Synchronization**

### 36.5.2 Data Ordering

The RGB color space format is required for viewing images on a display screen preview, and the YCbCr color space format is required for encoding.

All the sensors do not output the YCbCr or RGB components in the same order. The ISI allows the user to program the same component order as the sensor, reducing software treatments to restore the right format.

**Table 36-2. Data Ordering in YCbCr Mode**

| Mode    | Byte 0 | Byte 1 | Byte 2 | Byte 3 |
|---------|--------|--------|--------|--------|
| Default | Cb(i)  | Y(i)   | Cr(i)  | Y(i+1) |
| Mode 1  | Cr(i)  | Y(i)   | Cb(i)  | Y(i+1) |
| Mode 2  | Y(i)   | Cb(i)  | Y(i+1) | Cr(i)  |
| Mode 3  | Y(i)   | Cr(i)  | Y(i+1) | Cb(i)  |

**Table 36-3. RGB Format in Default Mode, RGB\_CFG = 00, No Swap**

| Mode      | Byte   | D7      | D6      | D5      | D4      | D3      | D2      | D1      | D0      |

|           | Byte 1 | G0(i)   | G1(i)   | G2(i)   | G3(i)   | G4(i)   | G5(i)   | G6(i)   | G7(i)   |
|           | Byte 2 | B0(i)   | B1(i)   | B2(i)   | B3(i)   | B4(i)   | B5(i)   | B6(i)   | B7(i)   |
|           | Byte 3 | R0(i+1) | R1(i+1) | R2(i+1) | R3(i+1) | R4(i+1) | R5(i+1) | R6(i+1) | R7(i+1) |
| RGB 5:6:5 | Byte 0 | G3(i)   | G4(i)   | G5(i)   | R0(i)   | R1(i)   | R2(i)   | R3(i)   | R4(i)   |
|           | Byte 1 | B0(i)   | B1(i)   | B2(i)   | B3(i)   | B4(i)   | G0(i)   | G1(i)   | G2(i)   |
|           | Byte 2 | G3(i+1) | G4(i+1) | G5(i+1) | R0(i+1) | R1(i+1) | R2(i+1) | R3(i+1) | R4(i+1) |
|           | Byte 3 | B0(i+1) | B1(i+1) | B2(i+1) | B3(i+1) | B4(i+1) | G0(i+1) | G1(i+1) | G2(i+1) |

The RGB 5:6:5 input format is processed to be displayed as RGB 5:6:5 format, compliant with the 16-bit mode of the LCD controller.

### 36.5.3 Clocks

The sensor Host clock (ISI\_MCK) can be generated either by the Power Management Controller (PMC) through a Programmable Clock output (using PID=59) or by an external oscillator connected to the sensor.

None of the sensors embed a power management controller, so providing the clock by the APMC is a simple and efficient way to control power consumption of the system.

Care must be taken when programming the system clock. The ISI has two clock domains, the sensor Host clock and the pixel clock provided by sensor. The two clock domains are not synchronized, but the sensor Host clock must be faster than the pixel clock.

### 36.5.4 Preview Path

#### 36.5.4.1 Scaling, Decimation (Subsampling)

This module resizes captured 8-bit color sensor images to fit the LCD display format. The resize module performs only downscaling. The same ratio is applied for both horizontal and vertical resize, then a fractional decimation algorithm is applied.

The decimation factor is a multiple of 1/16; values 0 to 15 are forbidden.

**Table 36-6. Decimation Factor**

|                   |      |    |       |       |       |     |       |       |       |       |
|-------------------|------|----|-------|-------|-------|-----|-------|-------|-------|-------|
| Decimation Value  | 0–15 | 16 | 17    | 18    | 19    | ... | 124   | 125   | 126   | 127   |
| Decimation Factor | —    | 1  | 1.063 | 1.125 | 1.188 | ... | 7.750 | 7.813 | 7.875 | 7.938 |

**Table 36-7. Decimation and Scaler Offset Values**

| OUTPUT            | INPUT | 352 × 288 | 640 × 480 | 800 × 600 | 1280 × 1024 | 1600 × 1200 | 2048 × 1536 |
|-------------------|-------|-----------|-----------|-----------|-------------|-------------|-------------|
| VGA<br>640 × 480  | F     | —         | 16        | 20        | 32          | 40          | 51          |
| QVGA<br>320 × 240 | F     | 16        | 32        | 40        | 64          | 80          | 102         |
| CIF<br>352 × 288  | F     | 16        | 26        | 33        | 56          | 66          | 85          |
| QCIF<br>176 × 144 | F     | 32        | 53        | 66        | 113         | 133         | 170         |

Example:

Input 1280 × 1024 Output = 640 × 480

Hratio = 1280/640 = 2

Vratio = 1024/480 = 2.1333

The decimation factor is 2 so 32/16.

**Figure 36-5. Resize Examples**

### 36.5.4.2 Color Space Conversion

This module converts YCrCb or YUV pixels to RGB color space. Clipping is performed to ensure that the samples value do not exceed the allowable range. The conversion matrix is defined below and is fully programmable:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} C_0 & 0 & C_1 \\ C_0 & -C_2 & -C_3 \\ C_0 & C_4 & 0 \end{bmatrix} \times \begin{bmatrix} Y - Y_{\text{off}} \\ C_b - C_{\text{boff}} \\ C_r - C_{\text{roff}} \end{bmatrix}$$

Example of programmable value to convert YCrCb to RGB:

$$\begin{cases} R = 1.164 \cdot (Y - 16) + 1.596 \cdot (C_r - 128) \\ G = 1.164 \cdot (Y - 16) - 0.813 \cdot (C_r - 128) - 0.392 \cdot (C_b - 128) \\ B = 1.164 \cdot (Y - 16) + 2.107 \cdot (C_b - 128) \end{cases}$$

An example of programmable value to convert from YUV to RGB:

$$\begin{cases} R = Y + 1.596 \cdot V \\ G = Y - 0.394 \cdot U - 0.436 \cdot V \\ B = Y + 2.032 \cdot U \end{cases}$$

### 36.5.4.3 Memory Interface

#### 36.5.4.3.1 RGB Mode

The preview datapath contains a data formatter that converts 8:8:8 pixel to RGB 5:6:5 format compliant with the 16-bit format of the LCD controller. In general, when converting from a color channel with more bits to one with fewer bits, the formatter module discards the lower-order bits.

For example, converting from RGB 8:8:8 to RGB 5:6:5, the formatter module discards the three LSBs from the red and blue channels, and two LSBs from the green channel.

#### 36.5.4.3.2 12-bit Grayscale Mode

ISI\_DATA[11:0] is the physical interface to the ISI. These bits are sampled and written to memory.

When 12-bit Grayscale mode is enabled, two memory formats are supported:

ISI\_CFG2.GS\_MODE = 0: two pixels per word

ISI\_CFG2.GS\_MODE = 1: one pixel per word

The following tables illustrate the memory mapping for the two formats.

If ISI\_CFG1.GRAYLE = 0, the pixels map as follows:

**Table 36-8. Grayscale Memory Mapping Configuration for 12-bit Data (ISI\_CFG2.GS\_MODE = 0: two pixels per word)**

|                |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| Pixel 0 [11:4] |    |    |    |    |    |    |    |
| 23             | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Pixel 0 [3:0]  |    |    |    | –  | –  | –  | –  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| Pixel 1 [11:4] |    |    |    |    |    |    |    |
| 7              | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Pixel 1 [3:0]  |    |    |    | –  | –  | –  | –  |

If ISI\_CFG1.GRAYLE=1, the pixels map as follows:

**Table 36-9. Grayscale Memory Mapping Configuration for 12-bit Data (ISI\_CFG2.GS\_MODE = 0: two pixels per word)**

|                |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| Pixel 1 [11:4] |    |    |    |    |    |    |    |
| 23             | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Pixel 1 [3:0]  |    |    |    | –  | –  | –  | –  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| Pixel 0 [11:4] |    |    |    |    |    |    |    |
| 7              | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Pixel 0 [3:0]  |    |    |    | –  | –  | –  | –  |

**Table 36-10. Grayscale Memory Mapping Configuration for 12-bit Data (ISI\_CFG2.GS\_MODE = 1: one pixel per word)**

|                |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| Pixel 0 [11:4] |    |    |    |    |    |    |    |
| 23             | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Pixel 0 [3:0]  |    |    |    | –  | –  | –  | –  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| –              | –  | –  | –  | –  | –  | –  | –  |
| 7              | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| –              | –  | –  | –  | –  | –  | –  | –  |

### 36.5.4.3.3 8-bit Grayscale Mode

For 8-bit Grayscale mode, ISI\_DATA[7:0] on the 12-bit data bus is the physical interface to the ISI. These bits are sampled and written to memory.

To enable 8-bit Grayscale mode, configure ISI\_CFG2 as follows:

- Clear ISI\_CFG2.GRAYSCALE.
- Clear ISI\_CFG2.RGB\_SWAP.
- Clear ISI\_CFG2.COL\_SPACE.
- Configure the field ISI\_CFG2.YCC\_SWAP to value 0.
- Configure the field ISI\_CFG2.IM\_VSIZE with the vertical resolution of the image minus 1.
- Configure the field ISI\_CFG2.IM\_HSIZE with the horizontal resolution of the image divided by 2. The horizontal resolution must be a multiple of 2.

The codec datapath is used to capture the 8-bit grayscale image. Use the following configuration:

- Set ISI\_DMA\_C\_CTRL.C\_FETCH.
- Configure ISI\_DMA\_C\_DSCR.C\_DSCR with the descriptor address.
- Write a one to the bit ISI\_DMA\_CHER.C\_CH\_EN.

**Table 36-11. Memory Mapping for 8-bit Grayscale Mode**

|         |    |    |    |    |    |    |    |
|---------|----|----|----|----|----|----|----|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| Pixel 3 |    |    |    |    |    |    |    |
| 23      | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Pixel 2 |    |    |    |    |    |    |    |
| 15      | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| Pixel 1 |    |    |    |    |    |    |    |
| 7       | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Pixel 0 |    |    |    |    |    |    |    |

### 36.5.4.4 FIFO and DMA Features

Both preview and codec datapaths contain FIFOs. These asynchronous buffers are used to safely transfer formatted pixels from the pixel clock domain to the AHB clock domain. A video arbiter is used to manage FIFO thresholds and triggers a relevant DMA request through the AHB Host interface. Thus, depending on the FIFO state, a specified length burst is asserted. Regarding AHB Host interface, it supports Scatter DMA mode through linked list operation.

This mode of operation improves flexibility of image buffer location and allows the user to allocate two or more frame buffers. The destination frame buffers are defined by a series of Frame Buffer Descriptors (FBD). Each FBD controls the transfer of one entire frame and then optionally loads a further FBD to switch the DMA operation at another frame buffer address. The FBD is defined by a series of three words. The first word defines the current frame buffer address (named DMA\_X\_ADDR register), the second defines control information (named DMA\_X\_CTRL register) and the third defines the next descriptor address (named DMA\_X\_DSCR). DMA Transfer mode with linked list support is available for both codec and preview datapaths. The data to be transferred described by an FBD requires several burst accesses. In the following example, the use of two ping-pong frame buffers is described.

Example:

The first FBD, stored at address 0x00030000, defines the location of the first frame buffer. This address is programmed in the ISI user interface DMA\_P\_DSCR. To enable the descriptor fetch operation, the value 0x00000001 must be written to the DMA\_P\_CTRL register. LLI\_0 and LLI\_1 are the two descriptors of the linked list.

Destination address: frame buffer ID0 0x02A000 (LLI\_0.DMA\_P\_ADDR)

Transfer 0 Control Information, fetch and writeback: 0x00000003 (LLI\_0.DMA\_P\_CTRL)

Next FBD address: 0x00030010 (LLI\_0.DMA\_P\_DSCR)

The second FBD, stored at address 0x00030010, defines the location of the second frame buffer.

Destination address: frame buffer ID1 0x0003A000 (LLI\_1.DMA\_P\_ADDR)

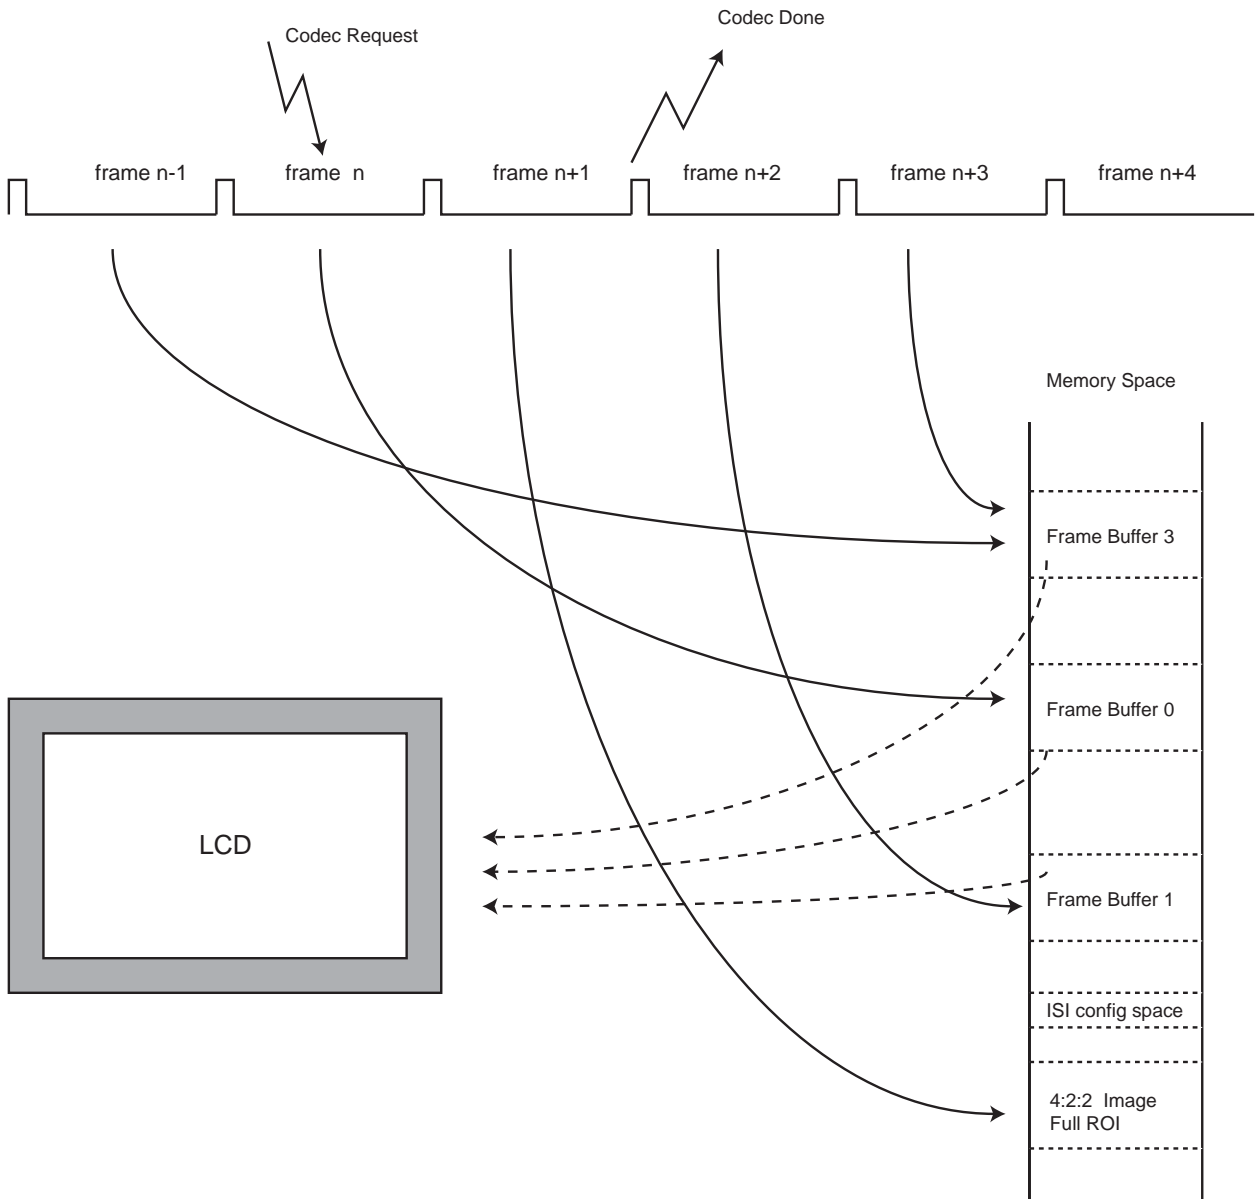

Transfer 1 Control information fetch and writeback: 0x00000003 (LLI\_1.DMA\_P\_CTRL)

The third FBD address: 0x00030000, wrapping to first FBD (LLI\_1.DMA\_P\_DSCR)

Using this technique, several frame buffers can be configured through the linked list. The following figure illustrates a typical three-frame buffer application. Frame n is mapped to frame buffer 0, frame n+1 is mapped to frame buffer 1, frame n+2 is mapped to frame buffer 2 and further frames wrap. A codec request occurs, and the full-size 4:2:2 encoded frame is stored in a dedicated memory space.

**Figure 36-6. Three Frame Buffers Application and Memory Mapping**

### 36.5.5 Codec Path

#### 36.5.5.1 Color Space Conversion

Depending on user selection, this module can be bypassed so that input YCrCb stream is directly connected to the format converter module. If the RGB input stream is selected, this module converts RGB to YCrCb color space with the formulas given below:

$$\begin{bmatrix} Y \\ C_r \\ C_b \end{bmatrix} = \begin{bmatrix} C_0 & C_1 & C_2 \\ C_3 & -C_4 & -C_5 \\ -C_6 & -C_7 & C_8 \end{bmatrix} \times \begin{bmatrix} R \\ G \\ B \end{bmatrix} + \begin{bmatrix} Y_{\text{off}} \\ C_{r\text{off}} \\ C_{b\text{off}} \end{bmatrix}$$

An example of coefficients is given below:

$$\begin{cases} Y = 0.257 \cdot R + 0.504 \cdot G + 0.098 \cdot B + 16 \\ C_r = 0.439 \cdot R - 0.368 \cdot G - 0.071 \cdot B + 128 \\ C_b = -0.148 \cdot R - 0.291 \cdot G + 0.439 \cdot B + 128 \end{cases}$$

### 36.5.5.2 Memory Interface

Dedicated FIFOs are used to support packed memory mapping. YCrCb pixel components are sent in a single 32-bit word in a contiguous space (packed). Data is stored in the order of natural scan lines. Planar mode is not supported.

### 36.5.5.3 DMA Features

Like preview datapath, codec datapath DMA mode uses linked list operation.

### 36.6 Register Summary

**Note:** Several parts of the ISI controller use the pixel clock provided by the image sensor (ISI\_PCK). Thus the user must first program the image sensor to provide this clock (ISI\_PCK) before programming the Image Sensor Controller.

| Offset | Name         | Bit Pos. | 7               | 6        | 5             | 4          | 3         | 2              | 1              | 0               |           |         |       |

| Access |     | R/W         | R/W      | R/W    | R/W        | R/W        | R/W       |     |     |
| Reset  |     | 0           | 0        | 0      | 0          | 0          | 0         |     |     |

**Bits 31:24 – SFD[7:0]** Start of Frame Delay  
SFD lines are skipped at the beginning of the frame.

**Bits 23:16 – SLD[7:0]** Start of Line Delay  
SLD pixel clock periods to wait before the beginning of a line.

**Bits 14:13 – THMASK[1:0]** Threshold Mask

| Value | Name     | Description                          |
|-------|----------|--------------------------------------|
| 0     | BEATS_4  | Only 4 beats AHB burst allowed       |
| 1     | BEATS_8  | Only 4 and 8 beats AHB burst allowed |
| 2     | BEATS_16 | 4, 8 and 16 beats AHB burst allowed  |

**Bit 12 – FULL** Full Mode is Allowed

| Value | Description  |
|-------|--|
| 0     | The codec frame is transferred to memory when an available frame slot is detected. |
| 1     | Both preview and codec DMA channels are operating simultaneously.                  |

**Bit 11 – DISCR** Disable Codec Request

| Value | Description   |
|-------|---|
| 0     | Codec datapath DMA interface requires a request to restart. |
| 1     | Codec datapath DMA automatically restarts.                  |

**Bits 10:8 – FRATE[2:0]** Frame Rate [0..7]

| Value | Description  |
|-------|--|
| 0     | All the frames are captured, else one frame every FRATE + 1 is captured. |

**Bit 7 – CRC\_SYNC** Embedded Synchronization Correction

| Value | Description  |
|-------|--|
| 0     | No CRC correction is performed on embedded synchronization.  |
| 1     | CRC correction is performed. If the correction is not possible, the current frame is discarded and the CRC_ERR bit is set in the ISI_SR. |

**Bit 6 – EMB\_SYNC** Embedded Synchronization

| Value | Description   |
|-------|---|
| 0     | Synchronization by HSYNC, VSYNC.                              |
| 1     | Synchronization by embedded synchronization sequence SAV/EAV. |

**Bit 5 – GRAYLE** Grayscale Little Endian

Refer to [Table 36-8](#) and [Table 36-9](#) for details.

| Value | Description  |
|-------|--|
| 0     | The two pixels are represented in big-endian format within a 32-bit register.    |
| 1     | The two pixels are represented in little-endian format within a 32-bit register. |

**Bit 4 – PIXCLK\_POL** Pixel Clock Polarity

| Value | Description                                     |
|-------|---|
| 0     | Data is sampled on rising edge of pixel clock.  |
| 1     | Data is sampled on falling edge of pixel clock. |

**Bit 3 – VSYNC\_POL** Vertical Synchronization Polarity

| Value | Description        |
|-------|--------------------|
| 0     | VSYNC active high. |
| 1     | VSYNC active low.  |

**Bit 2 – HSYNC\_POL** Horizontal Synchronization Polarity

| Value | Description        |
|-------|--------------------|
| 0     | HSYNC active high. |
| 1     | HSYNC active low.  |

### 36.6.2 ISI Configuration 2 Register

**Name:** ISI\_CFG2  
**Offset:** 0x04  
**Reset:** 0x00000000  
**Property:** Read/Write

| Reset  |     | 0             | 0        | 0             | 0        | 0       | 0              | 0   | 0   |

#### Bits 31:30 – RGB\_CFG[1:0] RGB Pixel Mapping Configuration

Defines RGB pattern when RGB\_MODE is set to 1.

If RGB\_MODE is set to RGB 8:8:8, then RGB\_CFG = 0 implies RGB color sequence, else it implies BGR color sequence.

| Value | Name    | Description  |
|-------|---------|--|
| 0     | DEFAULT | Byte 0 R/G(MSB)<br>Byte 1 G(LSB)/B<br>Byte 2 R/G(MSB)<br>Byte 3 G(LSB)/B |
| 1     | MODE1   | Byte 0 B/G(MSB)<br>Byte 1 G(LSB)/R<br>Byte 2 B/G(MSB)<br>Byte 3 G(LSB)/R |
| 2     | MODE2   | Byte 0 G(LSB)/R<br>Byte 1 B/G(MSB)<br>Byte 2 G(LSB)/R<br>Byte 3 B/G(MSB) |
| 3     | MODE3   | Byte 0 G(LSB)/B<br>Byte 1 R/G(MSB)<br>Byte 2 G(LSB)/B<br>Byte 3 R/G(MSB) |

**Bits 29:28 – YCC\_SWAP[1:0]** YCrCb Format Swap Mode

Defines the YCC image data.

| Value | Name    | Description  |
|-------|---------|--|
| 0     | DEFAULT | Byte 0 Cb(i)<br>Byte 1 Y(i)<br>Byte 2 Cr(i)<br>Byte 3 Y(i+1) |
| 1     | MODE1   | Byte 0 Cr(i)<br>Byte 1 Y(i)<br>Byte 2 Cb(i)<br>Byte 3 Y(i+1) |
| 2     | MODE2   | Byte 0 Y(i)<br>Byte 1 Cb(i)<br>Byte 2 Y(i+1)<br>Byte 3 Cr(i) |
| 3     | MODE3   | Byte 0 Y(i)<br>Byte 1 Cr(i)<br>Byte 2 Y(i+1)<br>Byte 3 Cb(i) |

**Bits 26:16 – IM\_HSIZE[10:0]** Horizontal Size of the Image Sensor [0..2047]

If 8-bit Grayscale mode is enabled, IM\_HSIZE = (Horizontal size/2) - 1.

Else IM\_HSIZE = Horizontal size - 1.

**Bit 15 – COL\_SPACE** Color Space for the Image Data

| Value | Description |
|-------|-------------|
| 0     | YCbCr.      |
| 1     | RGB.        |

**Bit 14 – RGB\_SWAP** RGB Format Swap Mode

The RGB\_SWAP has no effect when Grayscale mode is enabled.

| Value | Description |
|-------|-------------|
| 0     | D7 → R7.    |
| 1     | D0 → R7.    |

**Bit 13 – GRAYSCALE** Grayscale Mode Format Enable

| Value | Description                                   |
|-------|---|
| 0     | Grayscale mode is disabled.                   |
| 1     | Input image is assumed to be grayscale-coded. |

**Bit 12 – RGB\_MODE** RGB Input Mode

| Value | Description        |
|-------|--------------------|
| 0     | RGB 8:8:8 24 bits. |
| 1     | RGB 5:6:5 16 bits. |

**Bit 11 – GS\_MODE** Grayscale Pixel Format Mode

| Value | Description        |
|-------|--------------------|
| 0     | 2 pixels per word. |
| 1     | 1 pixel per word.  |

# SAM E70/S70/V70/V71

## Image Sensor Interface

---

---

**Bits 10:0 – IM\_VSIZE[10:0]** Vertical Size of the Image Sensor [0..2047]  
IM\_VSIZE = Vertical size - 1

### 36.6.3 ISI Preview Size Register

**Name:** ISI\_PSIZE  
**Offset:** 0x08  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 25:16 – PREV\_HSIZE[9:0]** Horizontal Size for the Preview Path  
PREV\_HSIZE = Horizontal Preview size - 1 (640 max only in RGB mode).

**Bits 9:0 – PREV\_VSIZE[9:0]** Vertical Size for the Preview Path  
PREV\_VSIZE = Vertical Preview size - 1 (480 max only in RGB mode).

**36.6.4 ISI Preview Decimation Factor Register**

**Name:** ISI\_PDECF  
**Offset:** 0x0C  
**Reset:** 0x00000010  
**Property:** Read/Write

**Bits 7:0 – DEC\_FACTOR[7:0]** Decimation Factor  
 DEC\_FACTOR is 8-bit width, range is from 16 to 255. Values from 0 to 16 do not perform any decimation.

### 36.6.5 ISI Color Space Conversion YCrCb to RGB Set 0 Register

**Name:** ISI\_Y2R\_SET0  
**Offset:** 0x10  
**Reset:** 0x6832CC95  
**Property:** Read/Write

**Bit 8 – ISI\_CDC** ISI Codec Request

Write a one to this bit to enable the codec datapath and capture a full resolution frame. A new request cannot be taken into account while CDC\_PND bit is active in the ISI\_SR.

**Bit 2 – ISI\_SRST** ISI Software Reset Request

Write a one to this bit to request a software reset of the module. Software must poll the SRST bit in the ISI\_SR to verify that the software request command has terminated.

**Bit 1 – ISI\_DIS** ISI Module Disable Request

Write a one to this bit to disable the module. If both ISI\_EN and ISI\_DIS are asserted at the same time, the disable request is not taken into account. Software must poll the DIS\_DONE bit in the ISI\_SR to verify that the command has successfully completed.

**Bit 0 – ISI\_EN** ISI Module Enable Request

Write a one to this bit to enable the module. Software must poll the ENABLE bit in the ISI\_SR to verify that the command has successfully completed.

| Reset  |     |    |    |    |    |        |         |       | 0         | 0         |         |
|        |     |    |    |    |    |        |         |       |           |           |         |
|        | Bit | 7  | 6  | 5  | 4  | 3      | 2       | 1     | 0         |           |         |
|        |     |    |    |    |    |        |         |       | SRST      | DIS_DONE  | ENABLE  |
| Access |     |    |    |    |    |        |         |       | R         | R         | R       |
| Reset  |     |    |    |    |    |        |         |       | 0         | 0         | 0       |

**Bit 27 – FR\_OVR** Frame Rate Overrun (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No frame overrun   |
| 1     | Frame overrun. The current frame is being skipped because a vsync signal has been detected while flushing FIFOs since the last read of ISI_SR. |

**Bit 26 – CRC\_ERR** CRC Synchronization Error (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No CRC error in the embedded synchronization frame (SAV/EAV)   |
| 1     | Embedded Synchronization Correction is enabled (CRC_SYNC bit is set) in the ISI_CR and an error has been detected and not corrected since the last read of ISI_SR. The frame is discarded and the ISI waits for a new one. |

**Bit 25 – C\_OVR** Codec Datapath Overflow (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No overflow  |
| 1     | An overrun condition has occurred in input FIFO on the codec path. The overrun happens when the FIFO is full and an attempt is made to write a new sample to the FIFO since the last read of ISI_SR. |

**Bit 24 – P\_OVR** Preview Datapath Overflow (cleared on read)

| Value | Description  |
|-------|--|
| 0     | No overflow  |
| 1     | An overrun condition has occurred in input FIFO on the preview path. The overrun happens when the FIFO is full and an attempt is made to write a new sample to the FIFO since the last read of ISI_SR. |

**Bit 19 – SIP** Synchronization in Progress

When the status of the preview or codec DMA channel is modified, a minimum amount of time is required to perform the clock domain synchronization.

| Value | Description   |
|-------|---|
| 0     | The clock domain synchronization process is terminated.   |
| 1     | This bit is set when the clock domain synchronization operation occurs. No modification of the channel status is allowed when this bit is set, to guarantee data integrity. |

**Bit 17 – CXFR\_DONE** Codec DMA Transfer has Terminated (cleared on read)

| Value | Description   |
|-------|---|
| 0     | Codec transfer done not detected.   |
| 1     | Codec transfer done detected. When set, this bit indicates that the data transfer on the codec channel has completed since the last read of ISI_SR. |

**Bit 16 – PXFR\_DONE** Preview DMA Transfer has Terminated (cleared on read)

| Value | Description   |
|-------|---|
| 0     | Preview transfer done not detected.   |
| 1     | Preview transfer done detected. When set, this bit indicates that the data transfer on the preview channel has completed since the last read of ISI_SR. |

**Bit 10 – VSYNC** Vertical Synchronization (cleared on read)

| Value | Description  |
|-------|--|
| 0     | Indicates that the vertical synchronization has not been detected since the last read of the ISI_SR. |
| 1     | Indicates that a vertical synchronization has been detected since the last read of the ISI_SR.       |

**Bit 8 – CDC\_PND** Pending Codec Request

| Value | Description   |
|-------|---|
| 0     | Indicates that no codec request is pending  |
| 1     | Indicates that the request has been taken into account but cannot be serviced within the current frame. The operation is postponed to the next frame. |

**Bit 2 – SRST** Module Software Reset Request has Terminated (cleared on read)

| Value | Description  |
|-------|--|
| 0     | Indicates that the request is not completed (if a request was issued).           |
| 1     | Software reset request has completed. This flag is reset after a read operation. |

**Bit 1 – DIS\_DONE** Module Disable Request has Terminated (cleared on read)

| Value | Description   |
|-------|---|
| 0     | Indicates that the request is not completed (if a request was issued).    |
| 1     | Disable request has completed. This flag is reset after a read operation. |

**Bit 0 – ENABLE** Module Enable

| Value | Description         |
|-------|---------------------|
| 0     | Module is disabled. |
| 1     | Module is enabled.  |

### 36.6.12 ISI Interrupt Enable Register

**Name:** ISI\_IER  
**Offset:** 0x2C  
**Reset:** –  
**Property:** Write-only

|        |     |    |    |    |    |        |         |           |           |  |

| Access |     |    |    |    |    |        |         | W         |           |  |
| Reset  |     |    |    |    |    |        |         | –         |           |  |
|        |     |    |    |    |    |        |         |           |           |  |
|        | Bit | 7  | 6  | 5  | 4  | 3      | 2       | 1         | 0         |  |
|        |     |    |    |    |    |        |         | SRST      | DIS_DONE  |  |
| Access |     |    |    |    |    |        |         | W         | W         |  |
| Reset  |     |    |    |    |    |        |         | –         | –         |  |

#### Bit 27 – FR\_OVR Frame Rate Overflow Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

#### Bit 26 – CRC\_ERR Embedded Synchronization CRC Error Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

#### Bit 25 – C\_OVR Codec Datapath Overflow Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

#### Bit 24 – P\_OVR Preview Datapath Overflow Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

#### Bit 17 – CXFR\_DONE Codec DMA Transfer Done Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

#### Bit 16 – PXFR\_DONE Preview DMA Transfer Done Interrupt Enable

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

---

---

| Value | Description                          |
|-------|--------------------------------------|
| 1     | Enables the corresponding interrupt. |

**Bit 10 – VSYNC** Vertical Synchronization Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

**Bit 2 – SRST** Software Reset Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

**Bit 1 – DIS\_DONE** Disable Done Interrupt Enable

| Value | Description                          |
|-------|--------------------------------------|
| 0     | No effect.                           |
| 1     | Enables the corresponding interrupt. |

### 36.6.13 ISI Interrupt Disable Register

**Name:** ISI\_IDR  
**Offset:** 0x30  
**Reset:** –  
**Property:** Write-only

|        |     |    |    |    |    |        |         |           |           |  |
|--------|-----|----|----|----|----|--------|---------|-----------|-----------|--|
|        | Bit | 31 | 30 | 29 | 28 | 27     | 26      | 25        | 24        |  |

|        |     |    |    |    |    |        | VSYNC   |           |           |  |
| Access |     |    |    |    |    |        | W       |           |           |  |
| Reset  |     |    |    |    |    |        | –       |           |           |  |
|        |     |    |    |    |    |        |         |           |           |  |
|        | Bit | 7  | 6  | 5  | 4  | 3      | 2       | 1         | 0         |  |
|        |     |    |    |    |    |        |         | SRST      | DIS_DONE  |  |
| Access |     |    |    |    |    |        |         | W         | W         |  |
| Reset  |     |    |    |    |    |        |         | –         | –         |  |

**Bit 27 – FR\_OVR** Frame Rate Overflow Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 26 – CRC\_ERR** Embedded Synchronization CRC Error Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 25 – C\_OVR** Codec Datapath Overflow Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 24 – P\_OVR** Preview Datapath Overflow Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 17 – CXFR\_DONE** Codec DMA Transfer Done Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 16 – PXFR\_DONE** Preview DMA Transfer Done Interrupt Disable

| Value | Description |
|-------|-------------|
| 0     | No effect.  |

---

---

| Value | Description                           |
|-------|---------------------------------------|
| 1     | Disables the corresponding interrupt. |

**Bit 10 – VSYNC** Vertical Synchronization Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 2 – SRST** Software Reset Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

**Bit 1 – DIS\_DONE** Disable Done Interrupt Disable

| Value | Description                           |
|-------|---------------------------------------|
| 0     | No effect.                            |
| 1     | Disables the corresponding interrupt. |

| Access |     |    |    |    |    |        |         | R         | R         |
| Reset  |     |    |    |    |    |        |         | 0         | 0         |

#### Bit 27 – FR\_OVR Frame Rate Overrun

| Value | Description                                   |
|-------|---|
| 0     | The Frame Rate Overrun interrupt is disabled. |
| 1     | The Frame Rate Overrun is enabled.            |

#### Bit 26 – CRC\_ERR CRC Synchronization Error

| Value | Description  |
|-------|--|
| 0     | The CRC Synchronization Error interrupt is disabled. |
| 1     | The CRC Synchronization Error interrupt is enabled.  |

#### Bit 25 – C\_OVR Codec FIFO Overflow

| Value | Description                                    |
|-------|--|
| 0     | The Codec FIFO Overflow interrupt is disabled. |
| 1     | The Codec FIFO Overflow interrupt is enabled.  |

#### Bit 24 – P\_OVR Preview FIFO Overflow

| Value | Description                                      |
|-------|--|
| 0     | The Preview FIFO Overflow interrupt is disabled. |
| 1     | The Preview FIFO Overflow interrupt is enabled.  |

#### Bit 17 – CXFR\_DONE Codec DMA Transfer Completed

| Value | Description   |
|-------|---|
| 0     | The Codec DMA Transfer Completed interrupt is disabled. |
| 1     | The Codec DMA Transfer Completed interrupt is enabled.  |

#### Bit 16 – PXFR\_DONE Preview DMA Transfer Completed

| Value | Description   |
|-------|---|
| 0     | The Preview DMA Transfer Completed interrupt is disabled. |

# SAM E70/S70/V70/V71

## Image Sensor Interface

---

---

| Value | Description  |
|-------|--|
| 1     | The Preview DMA Transfer Completed interrupt is enabled. |

### Bit 10 – VSYNC Vertical Synchronization

| Value | Description   |
|-------|---|
| 0     | The Vertical Synchronization interrupt is disabled. |
| 1     | The Vertical Synchronization interrupt is enabled.  |

### Bit 2 – SRST Software Reset Completed

| Value | Description   |
|-------|---|
| 0     | The Software Reset Completed interrupt is disabled. |
| 1     | The Software Reset Completed interrupt is enabled.  |

### Bit 1 – DIS\_DONE Module Disable Operation Completed

| Value | Description   |
|-------|---|
| 0     | The Module Disable Operation Completed interrupt is disabled. |
| 1     | The Module Disable Operation Completed interrupt is enabled.  |

### 36.6.15 DMA Channel Enable Register

**Name:** ISI\_DMA\_CHER  
**Offset:** 0x38  
**Reset:** –  
**Property:** Write-only

**Bit 1 – C\_CH\_EN** Codec Channel Enable  
Write a one to this bit to enable the codec DMA channel.

**Bit 0 – P\_CH\_EN** Preview Channel Enable  
Write a one to this bit to enable the preview DMA channel.

### 36.6.16 DMA Channel Disable Register

**Name:** ISI\_DMA\_CHDR  
**Offset:** 0x3C  
**Reset:** –  
**Property:** Write-only

**Bit 1 – C\_CH\_DIS** Codec Channel Disable Request

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Disables the channel. Poll C_CH_S in DMA_CHSR to verify that the codec channel status has been successfully modified. |

**Bit 0 – P\_CH\_DIS** Preview Channel Disable Request

| Value | Description   |
|-------|---|
| 0     | No effect.  |
| 1     | Disables the channel. Poll P_CH_S in DMA_CHSR to verify that the preview channel status has been successfully modified. |

### 36.6.17 DMA Channel Status Register

**Name:** ISI\_DMA\_CHSR  
**Offset:** 0x40  
**Reset:** 0x00000000  
**Property:** Read-only

**Bit 1 – C\_CH\_S** Code DMA Channel Status

| Value | Description                                       |
|-------|---|
| 0     | Indicates that the Codec DMA channel is disabled. |
| 1     | Indicates that the Codec DMA channel is enabled.  |

**Bit 0 – P\_CH\_S** Preview DMA Channel Status

| Value | Description   |
|-------|---|
| 0     | Indicates that the Preview DMA channel is disabled. |
| 1     | Indicates that the Preview DMA channel is enabled.  |

### 36.6.18 DMA Preview Base Address Register

**Name:** ISI\_DMA\_P\_ADDR  
**Offset:** 0x44  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |               |     |     |     |     |     |     |     |  |
|--------|-----|---------------|-----|-----|-----|-----|-----|-----|-----|--|

| Access |     | R/W           | R/W | R/W | R/W | R/W | R/W |     |     |  |
| Reset  |     | 0             | 0   | 0   | 0   | 0   | 0   |     |     |  |

**Bits 31:2 – P\_ADDR[29:0]** Preview Image Base Address  
 This address is word-aligned.

### 36.6.19 DMA Preview Control Register

**Name:** ISI\_DMA\_P\_CTRL  
**Offset:** 0x48  
**Reset:** 0x00000000  
**Property:** Read/Write

#### Bit 3 – P\_DONE Preview Transfer Done

This bit is only updated in the memory.

| Value | Description   |
|-------|---|
| 0     | The transfer related to this descriptor has not been performed.   |
| 1     | The transfer related to this descriptor has completed. This bit is updated in memory at the end of the transfer, when writeback operation is enabled. |

#### Bit 2 – P\_IEN Transfer Done Flag Control

| Value | Description  |
|-------|--|
| 0     | Preview transfer done flag generation is enabled.  |
| 1     | Preview transfer done flag generation is disabled. |

#### Bit 1 – P\_WB Descriptor Writeback Control Bit

| Value | Description                                      |
|-------|--|
| 0     | Preview channel writeback operation is disabled. |
| 1     | Preview channel writeback operation is enabled.  |

#### Bit 0 – P\_FETCH Descriptor Fetch Control Bit

| Value | Description                                  |
|-------|--|
| 0     | Preview channel fetch operation is disabled. |
| 1     | Preview channel fetch operation is enabled.  |

### 36.6.20 DMA Preview Descriptor Address Register

**Name:** ISI\_DMA\_P\_DSCR  
**Offset:** 0x4C  
**Reset:** 0x00000000  
**Property:** Read/Write

|        |     |               |     |     |     |     |     |     |     |  |

#### Bits 31:8 – WPKEY[23:0] Write Protection Key Password

| Value    | Name   | Description   |
|----------|--------|---|
| 0x495349 | PASSWD | Writing any other value in this field aborts the write operation of the WPEN bit.<br>Always reads as 0. |

#### Bit 0 – WPEN Write Protection Enable

| Value | Description  |
|-------|--|
| 0     | Disables the write protection if WPKEY corresponds to 0x495349 (“ISI” in ASCII). |
| 1     | Enables the write protection if WPKEY corresponds to 0x495349 (“ISI” in ASCII).  |

## **37. GMAC - Ethernet MAC**

The description and registers of this peripheral are using the 'GMAC' designation although the device does not support Gigabit Ethernet functionality.

### **37.1 Description**

The Ethernet Media Access Controller (GMAC) module implements a 10/100 Mbps Ethernet MAC, compatible with the IEEE 802.3 standard. The GMAC can operate in either half or full duplex mode at all supported speeds.

### **37.2 Embedded Characteristics**

- Compatible with IEEE Standard 802.3
- 10, 100 Mbps operation
- Full and half duplex operation at all supported speeds of operation
- Statistics Counter Registers for RMON/MIB
- MII/RMII interface to the physical layer
- Integrated physical coding
- Direct memory access (DMA) interface to external memory
- Support for priority queues in DMA
- 8-KByte transmit RAM and 4-KByte receive RAM (refer to [Table 37-4](#) for queue-specific sizes)
- Programmable burst length and endianism for DMA
- Interrupt generation to signal receive and transmit completion, errors or other events
- Automatic pad and cyclic redundancy check (CRC) generation on transmitted frames
- Automatic discard of frames received with errors
- Receive and transmit IP, TCP and UDP checksum offload. Both IPv4 and IPv6 packet types supported
- Address checking logic for four specific 48-bit addresses, four type IDs, promiscuous mode, hash matching of unicast and multicast destination addresses and Wake-on-LAN
- Management Data Input/Output (MDIO) interface for physical layer management
- Support for jumbo frames up to 10240 Bytes
- Full duplex flow control with recognition of incoming pause frames and hardware generation of transmitted pause frames
- Half duplex flow control by forcing collisions on incoming frames
- Support for 802.1Q VLAN tagging with recognition of incoming VLAN and priority tagged frames
- Support for 802.1Qbb priority-based flow control
- Programmable Inter Packet Gap (IPG) Stretch
- Recognition of IEEE 1588 PTP frames
- IEEE 1588 time stamp unit (TSU)
- Support for 802.1AS timing and synchronization
- Supports 802.1Qav traffic shaping on two highest priority queues
- Support for 802.3az Energy Efficient Ethernet

### 37.3 Block Diagram

Figure 37-1. Block Diagram

### 37.4 Signal Interface

The GMAC includes the following signal interfaces:

- MII, RMI to an external PHY
- MDIO interface for external PHY management
- Slave APB interface for accessing GMAC registers
- Master AHB interface for memory access
- GTSUCOMP signal for TSU timer count value comparison

Table 37-1. GMAC Connections in Different Modes

| Signal Name          | Function                          | MII      | RMI      |
|----------------------|-----------------------------------|----------|----------|
| GTXCK <sup>(1)</sup> | Transmit Clock or Reference Clock | TXCK     | REFCK    |
| GTXEN                | Transmit Enable                   | TXEN     | TXEN     |
| GTX[3..0]            | Transmit Data                     | TXD[3:0] | TXD[1:0] |
| GTXER                | Transmit Coding Error             | TXER     | Not Used |
| GRXCK                | Receive Clock                     | RXCK     | Not Used |
| GRXDV                | Receive Data Valid                | RXDV     | CRSDV    |
| GRX[3..0]            | Receive Data                      | RXD[3:0] | RXD[1:0] |
| GRXER                | Receive Error                     | RXER     | RXER     |
| GCRS                 | Carrier Sense and Data Valid      | CRS      | Not Used |
| GCOL                 | Collision Detect                  | COL      | Not Used |
| GMDC                 | Management Data Clock             | MDC      | MDC      |
| GMDIO                | Management Data Input/Output      | MDIO     | MDIO     |

**Note:**

1. Input only. GTXCK must be provided with a 25 MHz / 50 MHz external crystal oscillator for MII / RMII interfaces, respectively.

## 37.5 Product Dependencies

### 37.5.1 I/O Lines

The pins used for interfacing the GMAC may be multiplexed with PIO lines. The programmer must first program the PIO Controller to assign the pins to their peripheral function. If I/O lines of the GMAC are not used by the application, they can be used for other purposes by the PIO Controller.

### 37.5.2 Power Management

The GMAC is not continuously clocked. The user must first enable the GMAC clock in the Power Management Controller before using it.

### 37.5.3 Interrupt Sources

The GMAC interrupt line is connected to one of the internal sources of the interrupt controller. Using the GMAC interrupt requires prior programming of the interrupt controller.

The GMAC features interrupt sources. Refer to the table "Peripheral Identifiers" in the section "Peripherals" for the interrupt numbers for GMAC priority queues.

## 37.6 Functional Description

### 37.6.1 Media Access Controller

The Transmit Block of the Media Access Controller (MAC) takes data from FIFO, adds preamble, checks and adds padding and frame check sequence (FCS). Both half duplex and full duplex Ethernet modes of operation are supported.

When operating in half duplex mode, the MAC Transmit Block generates data according to the Carrier Sense Multiple Access with Collision Detect (CSMA/CD) protocol. The start of transmission is deferred if Carrier Sense (CRS) is active. If Collision (COL) is detected during transmission, a jam sequence is asserted and the transmission is retried after a random back off. The CRS and COL signals have no effect in full duplex mode.

The Receive Block of the MAC checks for valid preamble, FCS, alignment and length, and presents received frames to the MAC address checking block and FIFO. Software can configure the GMAC to receive jumbo frames of up to 10240 Bytes. It can optionally strip CRC (Cyclic Redundancy Check) from the received frame before transferring it to FIFO.

The Address Checker recognizes four specific 48-bit addresses, can recognize four different types of ID values, and contains a 64-bit Hash register for matching multicast and unicast addresses as required. It can recognize the broadcast address *all-'1'* (0xFFFFFFFF) and copy all frames. The MAC can also reject all frames that are not VLAN tagged, and recognize Wake on LAN events.

The MAC Receive Block supports offloading of IP, TCP and UDP checksum calculations (both IPv4 and IPv6 packet types supported), and can automatically discard bad checksum frames.

### 37.6.2 IEEE 1588 Time Stamp Unit

The IEEE 1588 time stamp unit (TSU) is implemented as a 94-bit timer.

- The 48 upper bits [93:46] of the timer count seconds and are accessible in the GMAC 1588 Timer Seconds High Register (GMAC\_TSH) and GMAC 1588 Timer Seconds Low Register (GMAC\_TSL).
- The 30 lower bits [45:16] of the timer count nanoseconds and are accessible in the GMAC 1588 Timer Nanoseconds Register (GMAC\_TN).
- The lowest 16 bits [15:0] of the timer count sub-nanoseconds.

The 46 lower bits roll over when they have counted to 1s. The timer increments by a programmable period (to approximately 15.2fs resolution) with each MCK period and can also be adjusted in 1ns resolution (incremented or decremented) through APB register accesses.

### 37.6.3 AHB Direct Memory Access Interface

The GMAC DMA controller is connected to the MAC FIFO interface and provides a scatter-gather type capability for packet data storage.

The DMA implements packet buffering where dual-port memories are used to buffer multiple frames.

#### 37.6.3.1 Packet Buffer DMA

- Easier to guarantee maximum line rate due to the ability to store multiple frames in the packet buffer, where the number of frames is limited by the amount of packet buffer memory and Ethernet frame size
- Full store and forward, or partial store and forward programmable options (partial store will cater for shorter latency requirements)
- Support for Transmit TCP/IP checksum offload
- Support for priority queuing
- When a collision on the line occurs during transmission, the packet will be automatically replayed directly from the packet buffer memory rather than having to re-fetch through the AHB (full store and forward ONLY)
- Received erroneous packets are automatically dropped before any of the packet is presented to the AHB (full store and forward ONLY), thus reducing AHB activity
- Supports manual RX packet flush capabilities
- Optional RX packet flush when there is lack of AHB resource

#### 37.6.3.2 Partial Store and Forward Using Packet Buffer DMA

The DMA uses SRAM-based packet buffers, and can be programmed into a low latency mode, known as Partial Store and Forward. This mode allows for a reduced latency as the full packet is not buffered before forwarding.

**Note:** This option is only available when the device is configured for full duplex operation.

This feature is enabled via the programmable TX and RX Partial Store and Forward registers (GMAC\_TPSF and GMAC\_RPSF). When the transmit Partial Store and Forward mode is activated, the transmitter will only begin to forward the packet to the MAC when there is enough packet data stored in the packet buffer. Likewise, when the receive Partial Store and Forward mode is activated, the receiver will only begin to forward the packet to the AHB when enough packet data is stored in the packet buffer. The amount of packet data required to activate the forwarding process is programmable via watermark registers. These registers are located at the same address as the partial store and forward enable bits.

**Note:** The minimum operational value for the TX partial store and forward watermark is 20. There is no operational limit for the RX partial store and forward watermark.

Enabling Partial Store and Forward is a useful means to reduce latency, but there are performance implications. The GMAC DMA uses separate transmit and receive lists of buffer descriptors, with each descriptor describing a buffer area in memory. This allows Ethernet packets to be broken up and scattered around the AHB memory space.

#### 37.6.3.3 Receive AHB Buffers

Received frames, optionally including FCS, are written to receive AHB buffers stored in memory. The receive buffer depth is programmable in the range of 64 Bytes to 16 KBytes through the DMA Configuration register (GMAC\_DCFGR), with the default being 128 Bytes.

The start location for each receive AHB buffer is stored in memory in a list of receive buffer descriptors at an address location pointed to by the receive buffer queue pointer. The base address for the receive buffer queue pointer is configured in software using the Receive Buffer Queue Base Address register (GMAC\_RBQB).

Each list entry consists of two words. The first is the address of the receive AHB buffer and the second the receive status.

If the length of a receive frame exceeds the AHB buffer length, the status word for the used buffer is written with zeroes except for the "Start of Frame" bit, which is always set for the first buffer in a frame.

Bit zero of the address field is written to 1 to show that the buffer has been used. The receive buffer manager then reads the location of the next receive AHB buffer and fills that with the next part of the received frame data. AHB

buffers are filled until the frame is complete and the final buffer descriptor status word contains the complete frame status. See the following table for details of the receive buffer descriptor list.

**Table 37-2. Receive Buffer Descriptor Entry**

| Bit    | Function   |
|--------|--|
| Word 0 |  |
| 31:2   | Address of beginning of buffer   |
| 1      | Wrap—marks last descriptor in receive buffer descriptor list.  |
| 0      | Ownership—needs to be zero for the GMAC to write data to the receive buffer. The GMAC sets this to one once it has successfully written a frame to memory. Software has to clear this bit before the buffer can be used again.   |
| Word 1 |  |
| 31     | Global all ones broadcast address detected   |
| 30     | Multicast hash match   |
| 29     | Unicast hash match   |
| 28     | –  |
| 27     | Specific Address Register match found, bit 25 and bit 26 indicate which Specific Address Register causes the match.  |
| 26:25  | Specific Address Register match. Encoded as follows:<br>00: Specific Address Register 1 match<br>01: Specific Address Register 2 match<br>10: Specific Address Register 3 match<br>11: Specific Address Register 4 match<br>If more than one specific address is matched only one is indicated with priority 4 down to 1.  |
| 24     | This bit has a different meaning depending on whether RX checksum offloading is enabled.<br>With RX checksum offloading disabled: (bit 24 clear in Network Configuration Register)<br>Type ID register match found, bit 22 and bit 23 indicate which type ID register causes the match.<br>With RX checksum offloading enabled: (bit 24 set in Network Configuration Register)<br>0: The frame was not SNAP encoded and/or had a VLAN tag with the Canonical Format Indicator (CFI) bit set.<br>1: The frame was SNAP encoded and had either no VLAN tag or a VLAN tag with the CFI bit not set. |

| .....continued |   |
|----------------|---|
| Bit            | Function  |
| 23:22          | <p>This bit has a different meaning depending on whether RX checksum offloading is enabled.</p> <p>With RX checksum offloading disabled: (bit 24 clear in Network Configuration)</p> <p>Type ID register match. Encoded as follows:</p> <p>00: Type ID register 1 match</p> <p>01: Type ID register 2 match</p> <p>10: Type ID register 3 match</p> <p>11: Type ID register 4 match</p> <p>If more than one Type ID is matched only one is indicated with priority 4 down to 1.</p> <p>With RX checksum offloading enabled: (bit 24 set in Network Configuration Register)</p> <p>00: Neither the IP header checksum nor the TCP/UDP checksum was checked.</p> <p>01: The IP header checksum was checked and was correct. Neither the TCP nor UDP checksum was checked.</p> <p>10: Both the IP header and TCP checksum were checked and were correct.</p> <p>11: Both the IP header and UDP checksum were checked and were correct.</p> |
| 21             | VLAN tag detected—type ID of 0x8100. For packets incorporating the stacked VLAN processing feature, this bit will be set if the second VLAN tag has a type ID of 0x8100   |
| 20             | Priority tag detected—type ID of 0x8100 and null VLAN identifier. For packets incorporating the stacked VLAN processing feature, this bit will be set if the second VLAN tag has a type ID of 0x8100 and a null VLAN identifier.  |
| 19:17          | VLAN priority—only valid if bit 21 is set.  |
| 16             | Canonical format indicator (CFI) bit (only valid if bit 21 is set).   |
| 15             | End of frame—when set the buffer contains the end of a frame. If end of frame is not set, then the only valid status bit is start of frame (bit 14).  |
| 14             | Start of frame—when set the buffer contains the start of a frame. If both bits 15 and 14 are set, the buffer contains a whole frame.  |
| 13             | <p>This bit has a different meaning depending on whether jumbo frames and ignore FCS modes are enabled. If neither mode is enabled this bit will be zero.</p> <p>With jumbo frame mode enabled: (bit 3 set in Network Configuration Register) Additional bit for length of frame (bit[13]), that is concatenated with bits[12:0]</p> <p>With ignore FCS mode enabled and jumbo frames disabled: (bit 26 set in Network Configuration Register and bit 3 clear in Network Configuration Register) This indicates per frame FCS status as follows:</p> <p>0: Frame had good FCS</p> <p>1: Frame had bad FCS, but was copied to memory as ignore FCS enabled.</p>  |
| 12:0           | <p>These bits represent the length of the received frame which may or may not include FCS depending on whether FCS discard mode is enabled.</p> <p>With FCS discard mode disabled: (bit 17 clear in Network Configuration Register)</p> <p>Least significant 12 bits for length of frame including FCS. If jumbo frames are enabled, these 12 bits are concatenated with bit[13] of the descriptor above.</p> <p>With FCS discard mode enabled: (bit 17 set in Network Configuration Register)</p> <p>Least significant 12 bits for length of frame excluding FCS. If jumbo frames are enabled, these 12 bits are concatenated with bit[13] of the descriptor above.</p>  |

Each receive AHB buffer start location is a word address. The start of the first AHB buffer in a frame can be offset by up to three Bytes, depending on the value written to bits 14 and 15 of the Network Configuration register (GMAC\_NCFGR). If the start location of the AHB buffer is offset, the available length of the first AHB buffer is reduced by the corresponding number of Bytes.

To receive frames, the AHB buffer descriptors must be initialized by writing an appropriate address to bits 31:2 in the first word of each list entry. Bit 0 must be written with zero. Bit 1 is the wrap bit and indicates the last entry in the buffer descriptor list.

The start location of the receive buffer descriptor list must be written with the receive buffer queue base address before reception is enabled (receive enable in the Network Control register GMAC\_NCR). Once reception is enabled, any writes to the Receive Buffer Queue Base Address register (GMAC\_RBQB) are ignored. When read, it will return the current pointer position in the descriptor list, though this is only valid and stable when receive is disabled.

If the filter block indicates that a frame should be copied to memory, the receive data DMA operation starts writing data into the receive buffer. If an error occurs, the buffer is recovered.

An internal counter within the GMAC represents the receive buffer queue pointer and it is not visible through the CPU interface. The receive buffer queue pointer increments by two words after each buffer has been used. It re-initializes to the receive buffer queue base address if any descriptor has its wrap bit set.

As receive AHB buffers are used, the receive AHB buffer manager sets bit zero of the first word of the descriptor to logic one indicating the AHB buffer has been used.

Software should search through the “used” bits in the AHB buffer descriptors to find out how many frames have been received, checking the start of frame and end of frame bits.

When the DMA is configured in the packet buffer Partial Store And Forward mode, received frames are written out to the AHB buffers as soon as enough frame data exists in the packet buffer. For both cases, this may mean several full AHB buffers are used before some error conditions can be detected. If a receive error is detected the receive buffer currently being written will be recovered. Previous buffers will not be recovered. As an example, when receiving frames with cyclic redundancy check (CRC) errors or excessive length, it is possible that a frame fragment might be stored in a sequence of AHB receive buffers. Software can detect this by looking for start of frame bit set in a buffer following a buffer with no end of frame bit set.

To function properly, a 10/100 Ethernet system should have no excessive length frames or frames greater than 128 Bytes with CRC errors. Collision fragments will be less than 128 Bytes long, therefore it will be a rare occurrence to find a frame fragment in a receive AHB buffer, when using the default value of 128 Bytes for the receive buffers size.

When in packet buffer full store and forward mode, only good received frames are written out of the DMA, so no fragments will exist in the AHB buffers due to MAC receiver errors. There is still the possibility of fragments due to DMA errors, for example used bit read on the second buffer of a multi-buffer frame.

If bit zero of the receive buffer descriptor is already set when the receive buffer manager reads the location of the receive AHB buffer, the buffer has been already used and cannot be used again until software has processed the frame and cleared bit zero. In this case, the “buffer not available” bit in the receive status register is set and an interrupt triggered. The receive resource error statistics register is also incremented.

When the DMA is configured in the packet buffer full store and forward mode, the user can optionally select whether received frames should be automatically discarded when no AHB buffer resource is available. This feature is selected via the DMA Discard Receive Packets bit in the DMA Configuration register (GMAC\_DCFGR.DDRP). By default, the received frames are not automatically discarded. If this feature is off, then received packets will remain to be stored in the SRAM-based packet buffer until AHB buffer resource next becomes available. This may lead to an eventual packet buffer overflow if packets continue to be received when bit zero (used bit) of the receive buffer descriptor remains set.

**Note:** After a used bit has been read, the receive buffer manager will re-read the location of the receive buffer descriptor every time a new packet is received. When the DMA is not configured in the packet buffer full store and forward mode and a used bit is read, the frame currently being received will be automatically discarded.

When the DMA is configured in the packet buffer full store and forward mode, a receive overrun condition occurs when the receive SRAM-based packet buffer is full, or because HRESP was not OK. In all other modes, a receive overrun condition occurs when either the AHB bus was not granted quickly enough, or because HRESP was not OK, or because a new frame has been detected by the receive block, but the status update or write back for the previous frame has not yet finished. For a receive overrun condition, the receive overrun interrupt is asserted and the buffer currently being written is recovered. The next frame that is received whose address is recognized reuses the buffer.

In any packet buffer mode, writing a '1' to the Flush Next Package bit in the NCR register (GMAC\_NCR.FNP) will force a packet from the external SRAM-based receive packet buffer to be flushed. This feature is only acted upon when the RX DMA is not currently writing packet data out to AHB, i.e., it is in an IDLE state. If the RX DMA is active, GMAC\_NCR.FNP=1 is ignored.

### 37.6.3.4 Transmit AHB Buffers

Frames to transmit are stored in one or more transmit AHB buffers. Transmit frames can be between 1 and 16384 Bytes long, so it is possible to transmit frames longer than the maximum length specified in the IEEE 802.3 standard. It should be noted that zero length AHB buffers are allowed and that the maximum number of buffers permitted for each transmit frame is 128.

The start location for each transmit AHB buffer is stored in memory in a list of transmit buffer descriptors at a location pointed to by the transmit buffer queue pointer. The base address for this queue pointer is set in software using the Transmit Buffer Queue Base Address register. Each list entry consists of two words. The first is the Byte address of the transmit buffer and the second containing the transmit control and status. For the packet buffer DMA, the start location for each AHB buffer is a Byte address, the bottom bits of the address being used to offset the start of the data from the data-word boundary (i.e., bits 2,1 and 0 are used to offset the address for 64-bit data paths). For the FIFO-based DMA configured with a 32-bit data path the address of the buffer is a Byte address.

For bus widths of 64 or 128-bits however, the address of the buffer must be aligned to the correct 64-bit or 128-bit boundary, plus an offset of less than 4 Bytes.

**Note:** This alignment restriction in FIFO-based DMA mode only should be sufficient for applications as the main purpose is to allow alignment of the encapsulated IP packet. Given the 14 Bytes of MAC encapsulation, an offset of 2 Bytes will always align the IP header to a 128-bit boundary.)

Frames can be transmitted with or without automatic Cyclic Redundancy Checksum (CRC) generation. If CRC is automatically generated, pad will also be automatically generated to take frames to a minimum length of 64 Bytes. When CRC is not automatically generated (as defined in word 1 of the transmit buffer descriptor), the frame is assumed to be at least 64 Bytes long and pad is not generated.

An entry in the transmit buffer descriptor list is described in this table:

**Table 37-3. Transmit Buffer Descriptor Entry**

| Bit    | Function   |
|--------|--|
| Word 0 |  |
| 31:0   | Byte address of buffer   |
| Word 1 |  |
| 31     | Used—must be zero for the GMAC to read data to the transmit buffer. The GMAC sets this to one for the first buffer of a frame once it has been successfully transmitted. Software must clear this bit before the buffer can be used again.   |
| 30     | Wrap—marks last descriptor in transmit buffer descriptor list. This can be set for any buffer within the frame.  |
| 29     | Retry limit exceeded, transmit error detected  |
| 28     | Transmit underrun—occurs when the start of packet data has been written into the FIFO and either HRESP is not OK, or the transmit data could not be fetched in time, or when buffers are exhausted.  |
| 27     | Transmit frame corruption due to AHB error—set if an error occurs while midway through reading transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame (if the buffers run out during transmission of a frame then transmission stops, FCS shall be bad and GTXER asserted). Also set if single frame is too large for configured packet buffer memory size. |
| 26     | Late collision, transmit error detected. Late collisions only force this status bit to be set in gigabit mode.   |
| 25:23  | Reserved   |

| .....continued |   |
|----------------|---|
| Bit            | Function  |
| 22:20          | Transmit IP/TCP/UDP checksum generation offload errors:<br>000: No Error.<br><br>001: The Packet was identified as a VLAN type, but the header was not fully complete, or had an error in it.<br><br>010: The Packet was identified as a SNAP type, but the header was not fully complete, or had an error in it.<br><br>011: The Packet was not of an IP type, or the IP packet was invalidly short, or the IP was not of type IPv4/IPv6.<br><br>100: The Packet was not identified as VLAN, SNAP or IP.<br><br>101: Non supported packet fragmentation occurred. For IPv4 packets, the IP checksum was generated and inserted.<br><br>110: Packet type detected was not TCP or UDP. TCP/UDP checksum was therefore not generated. For IPv4 packets, the IP checksum was generated and inserted.<br><br>111: A premature end of packet was detected and the TCP/UDP checksum could not be generated. |
| 19:17          | Reserved  |
| 16             | No CRC to be appended by MAC. When set, this implies that the data in the buffers already contains a valid CRC, hence no CRC or padding is to be appended to the current frame by the MAC.<br>This control bit must be set for the first buffer in a frame and will be ignored for the subsequent buffers of a frame.<br><br>Note that this bit must be clear when using the transmit IP/TCP/UDP checksum generation offload, otherwise checksum generation and substitution will not occur.  |
| 15             | Last buffer, when set this bit will indicate the last buffer in the current frame has been reached.   |
| 14             | Reserved  |
| 13:0           | Length of buffer  |

To transmit frames, the buffer descriptors must be initialized by writing an appropriate Byte address to bits [31:0] of the first word of each descriptor list entry.

The second word of the transmit buffer descriptor is initialized with control information that indicates the length of the frame, whether or not the MAC is to append CRC and whether the buffer is the last buffer in the frame.

After transmission the status bits are written back to the second word of the first buffer along with the used bit. Bit 31 is the used bit which must be zero when the control word is read if transmission is to take place. It is written to '1' once the frame has been transmitted. Bits[29:20] indicate various transmit error conditions. Bit 30 is the wrap bit which can be set for any buffer within a frame. If no wrap bit is encountered the queue pointer continues to increment.

The Transmit Buffer Queue Base Address register can only be updated while transmission is disabled or halted; otherwise any attempted write will be ignored. When transmission is halted the transmit buffer queue pointer will maintain its value. Therefore when transmission is restarted the next descriptor read from the queue will be from immediately after the last successfully transmitted frame. As long as transmit is disabled by writing a '0' to the Transmit Enable bit in the Network Control register (GMAC\_NCR.TXEN), the transmit buffer queue pointer resets to point to the address indicated by the Transmit Buffer Queue Base Address register (GMAC\_TBQB).

**Note:** Disabling receive does not have the same effect on the receive buffer queue pointer.

Once the transmit queue is initialized, transmit is activated by writing a '1' to the Start Transmission bit of the Network Control register (GMAC\_NCR.TSTART). Transmit is halted when a buffer descriptor with its used bit set is read, a transmit error occurs, or by writing to the Transmit Halt bit of the Network Control register (GMAC\_NCR.THALT). Transmission is suspended if a pause frame is received while the Transmit Pause Frame bit is '1' in the Network Configuration register (GMAC\_NCR.TXPF). Rewriting the Start bit (GMAC\_NCR.TSTART) while transmission is active is allowed. This is implemented by the Transmit Go variable which is readable in the Transmit Status register (GMAC\_TSR.TXGO). The TXGO variable is reset when:

- Transmit is disabled.

- A buffer descriptor with its ownership bit set is read.
- Bit 10, THALT, of the Network Control register is written.
- There is a transmit error such as too many retries, late collision (gigabit mode only) or a transmit underrun.

To set TXGO, write a '1' to GMAC\_NCR.TSTART. Transmit halt does not take effect until any ongoing transmit finishes.

The DMA transmission will automatically restart from the first buffer of the frame.

If the DMA is configured for packet buffer Partial Store and Forward mode and a collision occurs during transmission of a multi-buffer frame, transmission will automatically restart from the first buffer of the frame. For packet buffer mode, the entire contents of the frame are read into the transmit packet buffer memory, so the retry attempt will be replayed directly from the packet buffer memory rather than having to re-fetch through the AHB.

If a used bit is read midway through transmission of a multi-buffer frame, this is treated as a transmit error. Transmission stops, GTXER is asserted and the FCS will be bad.

If transmission stops due to a transmit error or a used bit being read, transmission restarts from the first buffer descriptor of the frame being transmitted when the transmit start bit is rewritten.

### 37.6.3.5 DMA Bursting on the AHB

The DMA will always use SINGLE, or INCR type AHB accesses for buffer management operations. When performing data transfers, the AHB burst length is selected by the Fixed Burst Length for DMA Data Operations bit field in the DMA Configuration register (GMAC\_DCFGR.FBLDO) so that either SINGLE or fixed length incrementing bursts (INCR4, INCR8 or INCR16) are used where possible:

When there is enough space and enough data to be transferred, the programmed fixed length bursts will be used. If there is not enough data or space available, for example when at the beginning or the end of a buffer, SINGLE type accesses are used. Also SINGLE type accesses are used at 1024 Byte boundaries, so that the 1 KByte boundaries are not burst over as per AHB requirements.

The DMA will not terminate a fixed length burst early, unless an error condition occurs on the AHB or if receive or transmit are disabled in the Network Control register (GMAC\_NCR).

### 37.6.3.6 DMA Packet Buffer

The DMA uses packet buffers for both transmit and receive paths. This mode allows multiple packets to be buffered in both transmit and receive directions. This allows the DMA to withstand far greater access latencies on the AHB and make more efficient use of the AHB bandwidth. There are two modes of operation—Full Store and Forward and Partial Store and Forward.

As described above, the DMA can be programmed into a low latency mode, known as Partial Store and Forward. For further details of this mode, see the related Links.

When the DMA is in full store and forward mode, full packets are buffered which provides the possibility to:

- Discard packets with error on the receive path before they are partially written out of the DMA, thus saving AHB bus bandwidth and driver processing overhead,
- Retry collided transmit frames from the buffer, thus saving AHB bus bandwidth,
- Implement transmit IP/TCP/UDP checksum generation offload.

With the packet buffers included, the structure of the GMAC data paths is shown in this image:

**Figure 37-2. Data Paths with Packet Buffers Included**

### 37.6.3.7 Transmit Packet Buffer

The transmitter packet buffer will continue attempting to fetch frame data from the AHB system memory until the packet buffer itself is full, at which point it will attempt to maintain its full level.

To accommodate the status and statistics associated with each frame, three words per packet (or two if the GMAC is configured in 64-bit data path mode) are reserved at the end of the packet data. If the packet is bad and requires to be dropped, the status and statistics are the only information held on that packet. Storing the status in the DPRAM is required in order to decouple the DMA interface of the buffer from the MAC interface, to update the MAC status/statistics and to generate interrupts in the order in which the packets that they represent were fetched from the AHB memory.

If any errors occur on the AHB while reading the transmit frame, the fetching of packet data from AHB memory is halted. The MAC transmitter will continue to fetch packet data, thereby emptying the packet buffer and allowing any good (non-erroneous) frames to be transmitted successfully. Once these have been fully transmitted, the status/statistics for the erroneous frame will be updated and software will be informed via an interrupt that an AHB error occurred. This way, the error is reported in the correct packet order.

The transmit packet buffer will only attempt to read more frame data from the AHB when space is available in the packet buffer memory. If space is not available it must wait until the a packet fetched by the MAC completes transmission and is subsequently removed from the packet buffer memory.

**Note:** If full store and forward mode is active and if a single frame is fetched that is too large for the packet buffer memory, the frame is flushed and the DMA halted with an error status. This is because a complete frame must be written into the packet buffer before transmission can begin, and therefore the minimum packet buffer memory size should be chosen to satisfy the maximum frame to be transmitted in the application.

In full store and forward mode, once the complete transmit frame is written into the packet buffer memory, a trigger is sent across to the MAC transmitter, which will then begin reading the frame from the packet buffer memory. Since the whole frame is present and stable in the packet buffer memory an underflow of the transmitter is not possible. The frame is kept in the packet buffer until notification is received from the MAC that the frame data has either been successfully transmitted or can no longer be retransmitted (too many retries in half duplex mode). When this

notification is received the frame is flushed from memory to make room for a new frame to be fetched from AHB system memory.

In Partial Store and Forward mode, a trigger is sent across to the MAC transmitter as soon as sufficient packet data is available, which will then begin fetching the frame from the packet buffer memory. If, after this point, the MAC transmitter is able to fetch data from the packet buffer faster than the AHB DMA can fill it, an underflow of the transmitter is possible. In this case, the transmission is terminated early, and the packet buffer is completely flushed. Transmission can only be restarted by writing a '1' to the Transmit Start bit in the Network Control register (GMAC\_NCR.TSTART).

In half duplex mode, the frame is kept in the packet buffer until notification is received from the MAC that the frame data has either been successfully transmitted or can no longer be retransmitted (too many retries in half duplex mode). When this notification is received the frame is flushed from memory to make room for a new frame to be fetched from AHB system memory.

In full duplex mode, the frame is removed from the packet buffer on the fly.

Other than underflow, the only MAC related errors that can occur are due to collisions during half duplex transmissions. When a collision occurs the frame still exists in the packet buffer memory so can be retried directly from there. After sixteen failed transmit attempts, the frame will be flushed from the packet buffer.

### 37.6.3.8 Receive Packet Buffer

The receive packet buffer stores frames from the MAC receiver along with their status and statistics. Frames with errors are flushed from the packet buffer memory, while good frames are pushed onto the DMA AHB interface.

The receiver packet buffer monitors the FIFO write interface from the MAC receiver and translates the FIFO pushes into packet buffer writes. At the end of the received frame the status and statistics are buffered so that the information can be used when the frame is read out. When programmed in full store and forward mode and the frame has an error, the frame data is immediately flushed from the packet buffer memory allowing subsequent frames to utilize the freed up space. The status and statistics for bad frames are still used to update the GMAC registers.

To accommodate the status and statistics associated with each frame, three words per packet (or two if configured in 64-bit datapath mode) are reserved at the end of the packet data. If the packet is bad and requires to be dropped, the status and statistics are the only information held on that packet.

The receiver packet buffer will also detect a full condition so that an overflow condition can be detected. If this occurs, subsequent packets are dropped and an RX overflow interrupt is raised.

For full store and forward, the DMA only begins packet fetches once the status and statistics for a frame are available. If the frame has a bad status due to a frame error, the status and statistics are passed on to the GMAC registers. If the frame has a good status, the information is used to read the frame from the packet buffer memory and burst onto the AHB using the DMA buffer management protocol. Once the last frame data has been transferred to the packet buffer, the status and statistics are updated to the GMAC registers.

If Partial Store and Forward mode is active, the DMA will begin fetching the packet data before the status is available. As soon as the status becomes available, the DMA will fetch this information as soon as possible before continuing to fetch the remainder of the frame. Once the last frame data has been transferred to the packet buffer, the status and statistics are updated to the GMAC registers.

### 37.6.3.9 Priority Queuing in the DMA

The DMA by default uses a single transmit and receive queue. This means the list of transmit/receive buffer descriptors point to data buffers associated with a single transmit/receive data stream. The GMAC can select up to priority queues. Each queue has an independent list of buffer descriptors pointing to separate data streams.

The table below gives the DPRAM size associated with each queue.

**Table 37-4. Queue Size**

| Queue Number         | Queue Size |
|----------------------|------------|
| 5 (highest priority) | 1 KB       |
| 4                    | 2 KB       |
| 3                    | 2 KB       |

| .....continued      |            |
|---------------------|------------|
| Queue Number        | Queue Size |
| 2                   | 512 bytes  |
| 1                   | 512 bytes  |
| 0 (lowest priority) | 2 KB       |

In the transmit direction, higher priority queues are always serviced before lower priority queues, with Q0 as lowest priority and Q as highest priority. This strict priority scheme requires the user to ensure that high priority traffic is constrained so that lower priority traffic will have required bandwidth. The GMAC DMA will determine the next queue to service by initiating a sequence of buffer descriptor reads interrogating the ownership bits of each. The buffer descriptor corresponding to the highest priority queue is read first.

As an example, if the ownership bit of this descriptor is set, the DMA will progress by reading the 2nd highest priority queue's descriptor. If that ownership bit read of this lower priority queue is set as well, the DMA will read the 3rd highest priority queue's descriptor. If all the descriptors return an ownership bit set, a resource error has occurred, so an interrupt is generated and transmission is automatically halted. Transmission can only be restarted by writing a '1' to the Transmission Start bit in the Network Control register (GMAC\_NCR.TSTART). The GMAC DMA will need to identify the highest available queue to transmit from when the TSTART bit is written and the TX is in a halted state, or when the last word of any packet has been fetched from external AHB memory.

The GMAC transmit DMA maximizes the effectiveness of priority queuing by ensuring that high priority traffic be transmitted as early as possible after being fetched from AHB. High priority traffic fetched from AHB will be pushed to the MAC layer, depending on traffic shaping being enabled and the associated credit value for that queue, before any lower priority traffic that may pre-exist in the transmit SRAM-based packet buffer. This is achieved by separating the transmit SRAM-based packet buffer into regions, one region per queue. The size of each region determines the amount of SRAM space allocated per queue.

For each queue, there is an associated Transmit Buffer Queue Base Address register (GMAC\_TBQB). For the lowest priority queue (or the only queue when only one queue is selected), the Transmit Buffer Queue Base Address is located at address 0x1C. For all other queues, the Transmit Buffer Queue Base Address registers are located at sequential addresses starting at address 0x440.

In the receive direction each packet is written to AHB data buffers in the order that it is received. For each queue, there is an independent set of receive AHB buffers for each queue. There is therefore a separate Receive Buffer Queue Base Address register for each queue (GMAC\_RBQBAX). For the lowest priority queue (or the only queue when only one queue is selected), the Receive Buffer Queue Base Address is located at address 0x18. For all other queues, the Receive Buffer Queue Base Address registers are located at sequential addresses starting at address 0x480. Every received packet will pass through a programmable screening algorithm which will allocate a particular queue to that frame. The user interface to the screeners is through two types of programmable registers:

- Screening Type 1 registers: The module features Screening Type 1 registers. Screening Type 1 registers hold values to match against specific IP and UDP fields of the received frames. The fields matched against are DS (Differentiated Services field of IPv4 frames), TC (Traffic class field of IPv6 frames) and/or the UDP destination port.
- Screening Type 2 registers: The module features Screening Type 2 registers GMAC\_ST2RPQ. Screening Type 2 registers operate independently of Screening Type 1 registers and offer additional match capabilities. Screening Type 2 allows a screen to be configured that is the combination of all or any of the following comparisons:
  - An enable bit VLAN priority, VLANE. A VLAN priority match will be performed if the VLAN priority enable is set. The extracted priority field in the VLAN header is compared against VLANP in the GMAC\_ST2RPQ itself.
  - An enable bit EtherType, ETHE. The EtherType field I2ETH inside the GMAC\_ST2RPQ maps to one of EtherType match registers, GMAC\_ST2ER. The extracted EtherType is compared against GMAC\_ST2ER designated by this EtherType field.
  - An enable bit Compare A, COMPAE. This bit is associated with a Screening Type 2 Compare Word 0/1 register x, GMAC\_ST2CW0/1.
  - An enable bit Compare B, COMPBE. This bit is associated with a Screening Type 2 Compare Word 0/1 register x, GMAC\_ST2CW0/1.

- An enable bit Compare C, COMPCE. This bit is associated with a Screening Type 2 Compare Word 0/1 register x, GMAC\_ST2CW0/1.

Each screener type has an enable bit, a match pattern and a queue number. If a received frame matches on an enabled screening register, then the frame will be tagged with the queue value in the associated screening register, and forwarded onto the DMA and subsequently into the external memory associated with that queue. If two screeners are matched then the one which resides at the lowest register address will take priority so care must be taken on the selection of the screener location.

When the priority queuing feature is enabled, the number of interrupt outputs from the GMAC core is increased to match the number of supported queues. The number of Interrupt Status registers is increased by the same number. Only DMA related events are reported using the individual interrupt outputs, as the GMAC can relate these events to specific queues. All other events generated within the GMAC are reported in the interrupt associated with the lowest priority queue. For the lowest priority queue (or the only queue when only 1 queue is selected), the Interrupt Status register is located at address 0x24. For all other queues, the Interrupt Status register is located at sequential addresses starting at address 0x400.

**Note:** The address matching is the first level of filtering. If there is a match, the screeners are the next level of filtering for routing the data to the appropriate queue. See [MAC Filtering Block](#) for more details.

The additional screening done by the functions Compare A, B, and C each have an enable bit and compare register field. COMPA, COMPB and COMPC in GMAC\_ST2RPQ are pointers to a configured offset (OFFSVAL), value (COMPVAL), and mask (MASKVAL). If enabled, the compare is true if the data at the offset into the frame, ANDed with MASKVAL, is equal to the value of COMPVAL ANDed with MASKVAL. A 16-bit word comparison is done. The byte at the offset number of bytes from the index start is compared to bits 7:0 of the configured COMPVAL and MASKVAL. The byte at the offset number of bytes + 1 from the index start is compared to bits 15:8 of the configured COMPVAL and MASKVAL.

The offset value in bytes, OFFSVAL, ranges from 0 to 127 bytes from either the start of the frame, the byte after the EtherType field, the byte after the IP header (IPv4 or IPv6) or the byte after the TCP/UDP header. Note the logic to decode the IP header or the TCP/UDP header is reused from the TCP/UDP/IP checksum offload logic and therefore has the same restrictions on use (the main limitation is that IP fragmentation is not supported). Refer to the Checksum Offload for IP, TCP and UDP section of this documentation for further details.

Compare A, B, and C use a common set of GMAC\_ST2CW0/1 registers, thus all COMPA, COMPB and COMPC fields in the registers GMAC\_ST2RPQ point to a single pool of GMAC\_ST2CW0/1 registers.

Note that Compare A, B and C together allow matching against an arbitrary 48 bits of data and so can be used to match against a MAC address.

All enabled comparisons are ANDed together to form the overall type 2 screening match.

### 37.6.4 MAC Transmit Block

The MAC transmitter can operate in either half duplex or full duplex mode and transmits frames in accordance with the Ethernet IEEE 802.3 standard. In half duplex mode, the CSMA/CD protocol of the IEEE 802.3 specification is followed.

A small input buffer receives data through the FIFO interface which will extract data in 32-bit form. All subsequent processing prior to the final output is performed in bytes.

Transmit data can be output using the MII interface.

Frame assembly starts by adding preamble and the start frame delimiter. Data is taken from the transmit FIFO interface a word at a time.

If necessary, padding is added to take the frame length to 60 bytes. CRC is calculated using an order 32-bit polynomial. This is inverted and appended to the end of the frame taking the frame length to a minimum of 64 bytes. If the no CRC bit is set in the second word of the last buffer descriptor of a transmit frame, neither pad nor CRC are appended. The no CRC bit can also be set through the FIFO interface.

In full duplex mode (at all data rates), frames are transmitted immediately. Back to back frames are transmitted at least 96 bit times apart to guarantee the interframe gap.

In half duplex mode, the transmitter checks carrier sense. If asserted, the transmitter waits for the signal to become inactive, and then starts transmission after the interframe gap of 96 bit times. If the collision signal is asserted during

transmission, the transmitter will transmit a jam sequence of 32 bits taken from the data register and then retry transmission after the back off time has elapsed. If the collision occurs during either the preamble or Start Frame Delimiter (SFD), then these fields will be completed prior to generation of the jam sequence.

The back off time is based on an XOR of the 10 least significant bits of the data coming from the transmit FIFO interface and a 10-bit pseudo random number generator. The number of bits used depends on the number of collisions seen. After the first collision 1 bit is used, then the second 2 bits and so on up to the maximum of 10 bits. All 10 bits are used above ten collisions. An error will be indicated and no further attempts will be made if 16 consecutive attempts cause collision. This operation is compliant with the description in Clause 4.2.3.2.5 of the IEEE 802.3 standard which refers to the truncated binary exponential back off algorithm.

In 10/100 mode, both collisions and late collisions are treated identically, and back off and retry will be performed up to 16 times. This condition is reported in the transmit buffer descriptor word 1 (late collision, bit 26) and also in the Transmit Status register (late collision, bit 7). An interrupt can also be generated (if enabled) when this exception occurs, and bit 5 in the Interrupt Status register will be set.

In all modes of operation, if the transmit DMA underruns, a bad CRC is automatically appended using the same mechanism as jam insertion and the GTXER signal is asserted. For a properly configured system this should never happen and also it is impossible if configured to use the DMA with packet buffers, as the complete frame is buffered in local packet buffer memory.

By setting when bit 28 is set in the Network Configuration register, the Inter Packet Gap (IPG) may be stretched beyond 96 bits depending on the length of the previously transmitted frame and the value written to the IPG Stretch register (GMAC\_IPGS). The least significant 8 bits of the IPG Stretch register multiply the previous frame length (including preamble). The next significant 8 bits (+1 so as not to get a divide by zero) divide the frame length to generate the IPG. IPG stretch only works in full duplex mode and when bit 28 is set in the Network Configuration register. The IPG Stretch register cannot be used to shrink the IPG below 96 bits.

If the back pressure bit is set in the Network Control register, or if the HD/FC configuration bit is set in the GMAC\_UR register (10M or 100M half duplex mode), the transmit block transmits 64 bits of data, which can consist of 16 nibbles of 1011 or in bit rate mode 64 1s, whenever it sees an incoming frame to force a collision. This provides a way of implementing flow control in half duplex mode.

### 37.6.5 MAC Receive Block

All processing within the MAC receive block is implemented using a 16-bit data path. The MAC receive block checks for valid preamble, FCS, alignment and length, presents received frames to the FIFO interface and stores the frame destination address for use by the address checking block.

If, during the frame reception, the frame is found to be too long, a bad frame indication is sent to the FIFO interface. The receiver logic ceases to send data to memory as soon as this condition occurs.

At end of frame reception the receive block indicates to the DMA block whether the frame is good or bad. The DMA block will recover the current receive buffer if the frame was bad.

Ethernet frames are normally stored in DMA memory complete with the FCS. Setting the FCS remove bit in the network configuration (bit 17) causes frames to be stored without their corresponding FCS. The reported frame length field is reduced by four bytes to reflect this operation.

The receive block signals to the register block to increment the alignment, CRC (FCS), short frame, long frame, jabber or receive symbol errors when any of these exception conditions occur.

If bit 26 is set in the network configuration, CRC errors will be ignored and CRC errored frames will not be discarded, though the Frame Check Sequence Errors statistic register will still be incremented. Additionally, if not enabled for jumbo frames mode, then bit[13] of the receiver descriptor word 1 will be updated to indicate the FCS validity for the particular frame. This is useful for applications such as EtherCAT whereby individual frames with FCS errors must be identified.

Received frames can be checked for length field error by setting the length field error frame discard bit of the Network Configuration register (bit-16). When this bit is set, the receiver compares a frame's measured length with the length field (bytes 13 and 14) extracted from the frame. The frame is discarded if the measured length is shorter. This checking procedure is for received frames between 64 bytes and 1518 bytes in length.

Each discarded frame is counted in the 10-bit length field error statistics register. Frames where the length field is greater than or equal to 0x0600 hex will not be checked.

### **37.6.6 Checksum Offload for IP, TCP and UDP**

The GMAC can be programmed to perform IP, TCP and UDP checksum offloading in both receive and transmit directions, which is enabled by setting bit 24 in the Network Configuration register for receive and bit 11 in the DMA Configuration register for transmit.

IPv4 packets contain a 16-bit checksum field, which is the 16-bit 1's complement of the 1's complement sum of all 16-bit words in the header. TCP and UDP packets contain a 16-bit checksum field, which is the 16-bit 1's complement of the 1's complement sum of all 16-bit words in the header, the data and a conceptual IP pseudo header.

To calculate these checksums in software requires each byte of the packet to be processed. For TCP and UDP this can use a large amount of processing power. Offloading the checksum calculation to hardware can result in significant performance improvements.

For IP, TCP or UDP checksum offload to be useful, the operating system containing the protocol stack must be aware that this offload is available so that it can make use of the fact that the hardware can either generate or verify the checksum.

#### **37.6.6.1 Receiver Checksum Offload**

When receive checksum offloading is enabled in the GMAC Network Configuration Register (NCFGR.RXCOEN), the IPv4 header checksum is checked as per RFC 791, where the packet meets the following criteria:

- If present, the VLAN header must be four octets long and the CFI bit must not be set.
- Encapsulation must be RFC 894 Ethernet Type Encoding or RFC 1042 SNAP Encoding.
- IPv4 packet
- IP header is of a valid length

The GMAC also checks the TCP checksum as per RFC 793, or the UDP checksum as per RFC 768, if the following criteria are met:

- IPv4 or IPv6 packet
- Good IP header checksum (if IPv4)
- No IP fragmentation
- TCP or UDP packet

When an IP, TCP or UDP frame is received, the receive buffer descriptor gives an indication if the GMAC was able to verify the checksums. There is also an indication if the frame had SNAP encapsulation. These indication bits will replace the type ID match indication bits when the receive checksum offload is enabled. For details of these indication bits refer to ["Receive Buffer Descriptor Entry"](#).

If any of the checksums are verified as incorrect by the GMAC, the packet is discarded and the appropriate statistics counter incremented.

#### **37.6.6.2 Transmitter Checksum Offload**

The transmitter checksum offload is only available if the full store and forward mode is enabled. This is because the complete frame to be transmitted must be read into the packet buffer memory before the checksum can be calculated and written back into the headers at the beginning of the frame.

Transmitter checksum offload is enabled by setting bit [11] in the DMA Configuration register. When enabled, it will monitor the frame as it is written into the transmitter packet buffer memory to automatically detect the protocol of the frame. Protocol support is identical to the receiver checksum offload.

For transmit checksum generation and substitution to occur, the protocol of the frame must be recognized and the frame must be provided without the FCS field, by making sure that bit [16] of the transmit descriptor word 1 is clear. If the frame data already had the FCS field, this would be corrupted by the substitution of the new checksum fields.

If these conditions are met, the transmit checksum offload engine will calculate the IP, TCP and UDP checksums as appropriate. Once the full packet is completely written into packet buffer memory, the checksums will be valid and the relevant DPRAM locations will be updated for the new checksum fields as per standard IP/TCP and UDP packet structures.

If the transmitter checksum engine is prevented from generating the relevant checksums, bits [22:20] of the transmitter DMA writeback status will be updated to identify the reason for the error. Note that the frame will still

be transmitted but without the checksum substitution, as typically the reason that the substitution did not occur was that the protocol was not recognized.

### 37.6.7 MAC Filtering Block

The filter block determines which frames should be written to the FIFO interface and on to the DMA.

Whether a frame is passed depends on what is enabled in the Network Configuration register, the state of the external matching pins, the contents of the specific address, type and Hash registers and the frame's destination address and type field.

If bit 25 of the Network Configuration register is not set, a frame will not be copied to memory if the GMAC is transmitting in half duplex mode at the time a destination address is received.

Ethernet frames are transmitted a byte at a time, least significant bit first. The first six bytes (48 bits) of an Ethernet frame make up the destination address. The first bit of the destination address, which is the LSB of the first byte of the frame, is the group or individual bit. This is one for multicast addresses and zero for unicast. The all ones address is the broadcast address and a special case of multicast.

The GMAC supports recognition of four specific addresses. Each specific address requires two registers, Specific Address register Bottom and Specific Address register Top. Specific Address register Bottom stores the first four bytes of the destination address and Specific Address register Top contains the last two bytes. The addresses stored can be specific, group, local or universal.

The destination address of received frames is compared against the data stored in the Specific Address registers once they have been activated. The addresses are deactivated at reset or when their corresponding Specific Address register Bottom is written. They are activated when Specific Address register Top is written. If a receive frame address matches an active address, the frame is written to the FIFO interface and on to DMA memory.

Frames may be filtered using the type ID field for matching. Four type ID registers exist in the register address space and each can be enabled for matching by writing a one to the MSB (bit 31) of the respective register. When a frame is received, the matching is implemented as an OR function of the various types of match.

The contents of each type ID register (when enabled) are compared against the length/type ID of the frame being received (e.g., bytes 13 and 14 in non-VLAN and non-SNAP encapsulated frames) and copied to memory if a match is found. The encoded type ID match bits (Word 0, Bit 22 and Bit 23) in the receive buffer descriptor status are set indicating which type ID register generated the match, if the receive checksum offload is disabled.

The reset state of the type ID registers is zero, hence each is initially disabled.

The following example illustrates the use of the address and type ID match registers for a MAC address of 21:43:65:87:A9:CB:

|                    |                       |
|--------------------|-----------------------|
| Preamble           | 55                    |
| SFD                | D5                    |
| DA (Octet 0 - LSB) | 21                    |
| DA (Octet 1)       | 43                    |
| DA (Octet 2)       | 65                    |
| DA (Octet 3)       | 87                    |
| DA (Octet 4)       | A9                    |
| DA (Octet 5 - MSB) | CB                    |
| SA (LSB)           | 00 (see <b>Note</b> ) |
| SA                 | 00(see <b>Note</b> )  |
| SA                 | 00(see <b>Note</b> )  |
| SA                 | 00(see <b>Note</b> )  |
| SA                 | 00(see <b>Note</b> )  |

|               |                      |
|---------------|----------------------|
| SA (MSB)      | 00(see <b>Note</b> ) |
| Type ID (MSB) | 43                   |
| Type ID (LSB) | 21                   |

**Note:** Contains the address of the transmitting device.

The previous sequence shows the beginning of an Ethernet frame. Byte order of transmission is from top to bottom, as shown. For a successful match to specific address 1, the following address matching registers must be set up:

Specific Address 1 Bottom register (GMAC\_SAB1) (Address 0x088) 0x87654321

Specific Address 1 Top register (GMAC\_SAT1) (Address 0x08C) 0x0000CBA9

For a successful match to the type ID, the following Type ID Match 1 register must be set up:

Type ID Match 1 register (GMAC\_TIDM1) (Address 0x0A8) 0x80004321

### 37.6.8 Broadcast Address

Frames with the broadcast address of 0xFFFFFFFF are stored to memory only if the 'no broadcast' bit in the Network Configuration register is set to zero.

### 37.6.9 Hash Addressing

The hash address register is 64 bits long and takes up two locations in the memory map. The least significant bits are stored in Hash Register Bottom and the most significant bits in Hash Register Top.

The unicast hash enable and the multicast hash enable bits in the Network Configuration register enable the reception of hash matched frames. The destination address is reduced to a 6-bit index into the 64-bit Hash register using the following hash function: The hash function is an XOR of every sixth bit of the destination address.

$$\text{hash\_index}[05] = \text{da}[05] \wedge \text{da}[11] \wedge \text{da}[17] \wedge \text{da}[23] \wedge \text{da}[29] \wedge \text{da}[35] \wedge \text{da}[41] \wedge \text{da}[47]$$

$$\text{hash\_index}[04] = \text{da}[04] \wedge \text{da}[10] \wedge \text{da}[16] \wedge \text{da}[22] \wedge \text{da}[28] \wedge \text{da}[34] \wedge \text{da}[40] \wedge \text{da}[46]$$

$$\text{hash\_index}[03] = \text{da}[03] \wedge \text{da}[09] \wedge \text{da}[15] \wedge \text{da}[21] \wedge \text{da}[27] \wedge \text{da}[33] \wedge \text{da}[39] \wedge \text{da}[45]$$

$$\text{hash\_index}[02] = \text{da}[02] \wedge \text{da}[08] \wedge \text{da}[14] \wedge \text{da}[20] \wedge \text{da}[26] \wedge \text{da}[32] \wedge \text{da}[38] \wedge \text{da}[44]$$

$$\text{hash\_index}[01] = \text{da}[01] \wedge \text{da}[07] \wedge \text{da}[13] \wedge \text{da}[19] \wedge \text{da}[25] \wedge \text{da}[31] \wedge \text{da}[37] \wedge \text{da}[43]$$

$$\text{hash\_index}[00] = \text{da}[00] \wedge \text{da}[06] \wedge \text{da}[12] \wedge \text{da}[18] \wedge \text{da}[24] \wedge \text{da}[30] \wedge \text{da}[36] \wedge \text{da}[42]$$

da[0] represents the least significant bit of the first byte received, that is, the multicast/unicast indicator, and da[47] represents the most significant bit of the last byte received.

If the hash index points to a bit that is set in the Hash register then the frame will be matched according to whether the frame is multicast or unicast.

A multicast match will be signaled if the multicast hash enable bit is set, da[0] is logic 1 and the hash index points to a bit set in the Hash register.

A unicast match will be signaled if the unicast hash enable bit is set, da[0] is logic 0 and the hash index points to a bit set in the Hash register.

To receive all multicast frames, the Hash register should be set with all ones and the multicast hash enable bit should be set in the Network Configuration register.

### 37.6.10 Copy all Frames (Promiscuous Mode)

If the Copy All Frames bit is set in the Network Configuration register then all frames (except those that are too long, too short, have FCS errors or have GRXER asserted during reception) will be copied to memory. Frames with FCS errors will be copied if bit 26 is set in the Network Configuration register.

### 37.6.11 Disable Copy of Pause Frames

Pause frames can be prevented from being written to memory by setting the disable copying of pause frames control bit 23 in the Network Configuration register. When set, pause frames are not copied to memory regardless of the

Copy All Frames bit, whether a hash match is found, a type ID match is identified or if a destination address match is found.

### 37.6.12 VLAN Support

The following table describes an Ethernet encoded 802.1Q VLAN tag.

**Table 37-5. 802.1Q VLAN Tag**

|  |   |
|--|---|
| TPID (Tag Protocol Identifier) 16 bits | TCI (Tag Control Information) 16 bits                 |
| 0x8100                                 | First 3 bits priority, then CFI bit, last 12 bits VID |

The VLAN tag is inserted at the 13th byte of the frame adding an extra four bytes to the frame. To support these extra four bytes, the GMAC can accept frame lengths up to 1536 bytes by setting bit 8 in the Network Configuration register.

If the VID (VLAN identifier) is null (0x000) this indicates a priority-tagged frame.

The following bits in the receive buffer descriptor status word give information about VLAN tagged frames:-

- Bit 21 set if receive frame is VLAN tagged (i.e., type ID of 0x8100).
- Bit 20 set if receive frame is priority tagged (i.e., type ID of 0x8100 and null VID). (If bit 20 is set, bit 21 will be set also.)
- Bit 19, 18 and 17 set to priority if bit 21 is set.
- Bit 16 set to CFI if bit 21 is set.

The GMAC can be configured to reject all frames except VLAN tagged frames by setting the discard non-VLAN frames bit in the Network Configuration register.

### 37.6.13 Wake on LAN Support

The receive block supports Wake on LAN by detecting the following events on incoming receive frames:

- Magic packet
- Address Resolution Protocol (ARP) request to the device IP address
- Specific address 1 filter match
- Multicast hash filter match

These events can be individually enabled through bits [19:16] of the Wake on LAN register. Also, for Wake on LAN detection to occur, receive enable must be set in the Network Control register, however a receive buffer does not have to be available.

In case of an ARP request, specific address 1 or multicast filter events will occur even if the frame is errored. For magic packet events, the frame must be correctly formed and error free.

A magic packet event is detected if all of the following are true:

- Magic packet events are enabled through bit 16 of the Wake on LAN register
- The frame's destination address matches specific address 1
- The frame is correctly formed with no errors
- The frame contains at least 6 bytes of 0xFF for synchronization
- There are 16 repetitions of the contents of Specific Address 1 register immediately following the synchronization

An ARP request event is detected if all of the following are true:

- ARP request events are enabled through bit 17 of the Wake on LAN register
- Broadcasts are allowed by bit 5 in the Network Configuration register
- The frame has a broadcast destination address (bytes 1 to 6)
- The frame has a type ID field of 0x0806 (bytes 13 and 14)
- The frame has an ARP operation field of 0x0001 (bytes 21 and 22)
- The least significant 16 bits of the frame's ARP target protocol address (bytes 41 and 42) match the value programmed in bits[15:0] of the Wake on LAN register

---

The decoding of the ARP fields adjusts automatically if a VLAN tag is detected within the frame. The reserved value of 0x0000 for the Wake on LAN target address value will not cause an ARP request event, even if matched by the frame.

A specific address 1 filter match event will occur if all of the following are true:

- Specific address 1 events are enabled through bit 18 of the Wake on LAN register
- The frame's destination address matches the value programmed in the Specific Address 1 registers

A multicast filter match event will occur if all of the following are true:

- Multicast hash events are enabled through bit 19 of the Wake on LAN register
- Multicast hash filtering is enabled through bit 6 of the Network Configuration register
- The frame destination address matches against the multicast hash filter
- The frame destination address is not a broadcast

### 37.6.14 IEEE 1588 Support

IEEE 1588 is a standard for precision time synchronization in local area networks. It works with the exchange of special Precision Time Protocol (PTP) frames. The PTP messages can be transported over IEEE 802.3/Ethernet, over Internet Protocol Version 4 or over Internet Protocol Version 6 as described in the annex of IEEE P1588.D2.1.

The GMAC indicates the message time-stamp point (asserted on the start packet delimiter and de-asserted at end of frame) for all frames and the passage of PTP event frames (asserted when a PTP event frame is detected and de-asserted at end of frame).

IEEE 802.1AS is a subset of IEEE 1588. One difference is that IEEE 802.1AS uses the Ethernet multicast address 0180C200000E for sync frame recognition whereas IEEE 1588 does not. GMAC is designed to recognize sync frames with both IEEE 802.1AS and IEEE 1588 addresses and so can support both 1588 and 802.1AS frame recognition simultaneously.

Synchronization between master and slave clocks is a two stage process.

First, the offset between the master and slave clocks is corrected by the master sending a sync frame to the slave with a follow up frame containing the exact time the sync frame was sent. Hardware assist modules at the master and slave side detect exactly when the sync frame was sent by the master and received by the slave. The slave then corrects its clock to match the master clock.

Second, the transmission delay between the master and slave is corrected. The slave sends a delay request frame to the master which sends a delay response frame in reply. Hardware assist modules at the master and slave side detect exactly when the delay request frame was sent by the slave and received by the master. The slave will now have enough information to adjust its clock to account for delay. For example, if the slave was assuming zero delay, the actual delay will be half the difference between the transmit and receive time of the delay request frame (assuming equal transmit and receive times) because the slave clock will be lagging the master clock by the delay time already.

The time-stamp is taken when the message time-stamp point passes the clock time-stamp point. This can generate an interrupt if enabled (GMAC\_IER). However, MAC Filtering configuration is needed to actually 'copy' the message to memory. For Ethernet, the message time-stamp point is the SFD and the clock time-stamp point is the MII interface. (The IEEE 1588 specification refers to sync and delay\_req messages as event messages as these require time-stamping. These events are captured in the registers GMAC\_EFTx and GMAC\_EFRx, respectively. Follow up, delay response and management messages do not require time-stamping and are referred to as general messages.)

1588 version 2 defines two additional PTP event messages. These are the peer delay request (Pdelay\_Req) and peer delay response (Pdelay\_Resp) messages. These events are captured in the registers GMAC\_PEFTx and GMAC\_PEFRx, respectively. These messages are used to calculate the delay on a link. Nodes at both ends of a link send both types of frames (regardless of whether they contain a master or slave clock). The Pdelay\_Resp message contains the time at which a Pdelay\_Req was received and is itself an event message. The time at which a Pdelay\_Resp message is received is returned in a Pdelay\_Resp\_Follow\_Up message.

1588 version 2 introduces transparent clocks of which there are two kinds, peer-to-peer (P2P) and end-to-end (E2E). Transparent clocks measure the transit time of event messages through a bridge and amend a correction field within the message to allow for the transit time. P2P transparent clocks additionally correct for the delay in the receive path of the link using the information gathered from the peer delay frames. With P2P transparent clocks delay\_req messages are not used to measure link delay. This simplifies the protocol and makes larger systems more stable.

The GMAC recognizes four different encapsulations for PTP event messages:

1. 1588 version 1 (UDP/IPv4 multicast)
2. 1588 version 2 (UDP/IPv4 multicast)
3. 1588 version 2 (UDP/IPv6 multicast)
4. 1588 version 2 (Ethernet multicast)

**Table 37-6. Example of Sync Frame in 1588 Version 1 Format**

| Frame Segment                 | Value                |
|-------------------------------|----------------------|
| Preamble/SFD                  | 55555555555555D5     |
| DA (Octets 0–5)               | —                    |
| SA (Octets 6–11)              | —                    |
| Type (Octets 12–13)           | 0800                 |
| IP stuff (Octets 14–22)       | —                    |
| UDP (Octet 23)                | 11                   |
| IP stuff (Octets 24–29)       | —                    |
| IP DA (Octets 30–32)          | E00001               |
| IP DA (Octet 33)              | 81 or 82 or 83 or 84 |
| Source IP port (Octets 34–35) | —                    |
| Dest IP port (Octets 36–37)   | 013F                 |
| Other stuff (Octets 38–42)    | —                    |
| Version PTP (Octet 43)        | 01                   |
| Other stuff (Octets 44–73)    | —                    |
| Control (Octet 74)            | 00                   |
| Other stuff (Octets 75–168)   | —                    |

**Table 37-7. Example of Delay Request Frame in 1588 Version 1 Format**

| Frame Segment                 | Value                |
|-------------------------------|----------------------|
| Preamble/SFD                  | 55555555555555D5     |
| DA (Octets 0–5)               | —                    |
| SA (Octets 6–11)              | —                    |
| Type (Octets 12–13)           | 0800                 |
| IP stuff (Octets 14–22)       | —                    |
| UDP (Octet 23)                | 11                   |
| IP stuff (Octets 24–29)       | —                    |
| IP DA (Octets 30–32)          | E00001               |
| IP DA (Octet 33)              | 81 or 82 or 83 or 84 |
| Source IP port (Octets 34–35) | —                    |
| Dest IP port (Octets 36–37)   | 013F                 |
| Other stuff (Octets 38–42)    | —                    |

.....continued

| Frame Segment               | Value |
|-----------------------------|-------|
| Version PTP (Octet 43)      | 01    |
| Other stuff (Octets 44–73)  | —     |
| Control (Octet 74)          | 01    |
| Other stuff (Octets 75–168) | —     |

For 1588 version 1 messages, sync and delay request frames are indicated by the GMAC if the frame type field indicates TCP/IP, UDP protocol is indicated, the destination IP address is 224.0.1.129/130/131 or 132, the destination UDP port is 319 and the control field is correct.

The control field is 0x00 for sync frames and 0x01 for delay request frames.

For 1588 version 2 messages, the type of frame is determined by looking at the message type field in the first byte of the PTP frame. Whether a frame is version 1 or version 2 can be determined by looking at the version PTP field in the second byte of both version 1 and version 2 PTP frames.

In version 2 messages sync frames have a message type value of 0x0, delay\_req have 0x1, Pdelay\_Req have 0x2 and Pdelay\_Resp have 0x3.

**Table 37-8. Example of Sync Frame in 1588 Version 2 (UDP/IPv4) Format**

| Frame Segment                 | Value            |

For the multicast address 011B19000000 sync and delay request frames are recognized depending on the message type field, 00 for sync and 01 for delay request.

**Table 37-12. Example of Sync Frame in 1588 Version 2 (Ethernet Multicast) Format**

| Frame Segment           | Value            |
|-------------------------|------------------|
| Preamble/SFD            | 55555555555555D5 |
| DA (Octets 0–5)         | 011B19000000     |
| SA (Octets 6–11)        | —                |

| Version PTP (Octet 15)  | 02               |

Pdelay request frames need a special multicast address so they can pass through ports blocked by the spanning tree protocol. For the multicast address 0180C200000E sync, Pdelay\_Req and Pdelay\_Resp frames are recognized depending on the message type field, 00 for sync, 02 for pdelay request and 03 for pdelay response.

**Table 37-13. Example of Pdelay\_Req Frame in 1588 Version 2 (Ethernet Multicast) Format**

| Frame Segment           | Value            |

| Type (Octets 12–13)     | 88F7             |
| Message type (Octet 14) | 00               |
| Version PTP (Octet 15)  | 02               |

### 37.6.15 Time Stamp Unit

#### Overview

The TSU consists of a timer and registers to capture the time at which PTP event frames cross the message timestamp point. An interrupt is issued when a capture register is updated.

The 1588 time stamp unit (TSU) is implemented as a 94-bit timer.

- The 48 upper bits [93:46] of the timer count seconds and are accessible in the GMAC 1588 Timer Seconds High Register (GMAC\_TSH) and GMAC 1588 Timer Seconds Low Register (GMACTSL).
- The 30 lower bits [45:16] of the timer count nanoseconds and are accessible in the GMAC 1588 Timer Nanoseconds Register (GMAC\_TN).
- The lowest 16 bits [15:0] of the timer count sub-nanoseconds.

The 46 lower bits roll over when they have counted to 1s. An interrupt is generated when the seconds increment. The timer increments by a programmable period (to approximately 15.2fs resolution) with each MCK period. The timer value can be read, written and adjusted with 1ns resolution (incremented or decremented) through the APB interface.

### Timer Adjustment

The amount by which the timer increments each clock cycle is controlled by the Timer Increment register (GMAC\_TI). Bits [7:0] are the default increment value in nanoseconds. Additional 16 bits of sub-nanosecond resolution are available using the Timer Increment Sub-Nanoseconds register (GMAC\_TISUBN). If the rest of the register is written with zero, the timer increments by the value in [7:0], plus the value of the GMAC\_TISUBN for each clock cycle.

The GMAC\_TISUBN allows a resolution of approximately 15fs.

Bits [15:8] of the increment register are the alternative increment value in nanoseconds, and bits [23:16] are the number of increments after which the alternative increment value is used. If [23:16] are zero the alternative increment value will never be used.

Taking the example of 10.2MHz, there are 102 cycles every 10µs or 51 cycles every 5µs. So a timer with a 10.2MHz clock source is constructed by incrementing by 98ns for fifty cycles and then incrementing by 100ns (98ns × 50 + 100ns = 5000ns). This is programmed by writing the value 0x00326462 to the Timer Increment register (GMAC\_TI).

In a second example, a 49.8 MHz clock source requires 20ns for 248 cycles, followed by an increment of 40ns (20ns × 248 + 40ns = 5000ns). This is programmed by writing the value 0x00F82814 to the GMAC\_TI register.

The Number of Increments bit field in the GMAC\_TI register is 8 bit in size, so frequencies up to 50MHz are supported with 200kHz resolution.

Without the alternative increment field the period of the clock would be limited to an integer number of nanoseconds, resulting in supported clock frequencies of 8, 10, 20, 25, 40, 50, 100, 125, 200 and 250 MHz.

There are six additional 62-bit registerseight additional 80-bit registers that capture the time at which PTP event frames are transmitted and received. An interrupt is issued when these registers are updated. The TSU timer count value can be compared to a programmable comparison value. For the comparison, the 48 bits of the seconds value and the upper 22 bits of the nanoseconds value are used. A signal (GTSUCOMP) is output from the core to indicate when the TSU timer count value is equal to the comparison value stored in the TSU timer comparison value registers (GMAC\_NSC, GMAC\_SCL, and GMAC\_SCH). The GTSUCOMP signal can be routed to the Timer peripheral to automatically toggle pin TIOA11/PD21. This can be used as the reference clock for an external PLL to regenerate the audio clock in Ethernet AVB. An interrupt can also be generated (if enabled) when the TSU timer count value and comparison value are equal, mapped to bit 29 of the interrupt status register.

### 37.6.16 MAC 802.3 Pause Frame Support

**Note:** Refer to the Clause 31, and Annex 31A and 31B of the IEEE standard 802.3 for a full description of MAC 802.3 pause operation.

The following table shows the start of a MAC 802.3 pause frame.

**Table 37-14. Start of an 802.3 Pause Frame**

| Address        |         | Type<br>(MAC Control Frame) | Pause  |         |
|----------------|---------|-----------------------------|--------|---------|
| Destination    | Source  |                             | Opcode | Time    |
| 0x0180C2000001 | 6 bytes | 0x8808                      | 0x0001 | 2 bytes |

The GMAC supports both hardware controlled pause of the transmitter, upon reception of a pause frame, and hardware generated pause frame transmission.

#### 37.6.16.1 802.3 Pause Frame Reception

Bit 13 of the Network Configuration register is the pause enable control for reception. If this bit is set, transmission will pause if a non zero pause quantum frame is received.

If a valid pause frame is received then the Pause Time register is updated with the new frame's pause time, regardless of whether a previous pause frame is active or not. An interrupt (either bit 12 or bit 13 of the Interrupt Status register) is triggered when a pause frame is received, but only if the interrupt has been enabled (bit 12 and bit 13 of the Interrupt Mask register). Pause frames received with non zero quantum are indicated through the interrupt bit 12 of the Interrupt Status register. Pause frames received with zero quantum are indicated on bit 13 of the Interrupt Status register.

Once the Pause Time register is loaded and the frame currently being transmitted has been sent, no new frames are transmitted until the pause time reaches zero. The loading of a new pause time, and hence the pausing of transmission, only occurs when the GMAC is configured for full duplex operation. If the GMAC is configured for half duplex there will be no transmission pause, but the pause frame received interrupt will still be triggered. A valid pause frame is defined as having a destination address that matches either the address stored in Specific Address register 1 or if it matches the reserved address of 0x0180C2000001. It must also have the MAC control frame type ID of 0x8808 and have the pause opcode of 0x0001.

Pause frames that have frame check sequence (FCS) or other errors will be treated as invalid and will be discarded. 802.3 Pause frames that are received after Priority-based Flow Control (PFC) has been negotiated will also be discarded. Valid pause frames received will increment the pause frames received statistic register.

The pause time register decrements every 512 bit times once transmission has stopped. For test purposes, the retry test bit can be set (bit 12 in the Network Configuration register) which causes the Pause Time register to decrement every GTXCK cycle once transmission has stopped.

The interrupt (bit 13 in the Interrupt Status register) is asserted whenever the Pause Time register decrements to zero (assuming it has been enabled by bit 13 in the Interrupt Mask register). This interrupt is also set when a zero quantum pause frame is received.

### 37.6.16.2 802.3 Pause Frame Transmission

Automatic transmission of pause frames is supported through the transmit pause frame bits of the Network Control register. If either bit 11 or bit 12 of the Network Control register is written with logic 1, an 802.3 pause frame will be transmitted, providing full duplex is selected in the Network Configuration register and the transmit block is enabled in the Network Control register.

Pause frame transmission will happen immediately if transmit is inactive or if transmit is active between the current frame and the next frame due to be transmitted.

Transmitted pause frames comprise the following:

- A destination address of 01-80-C2-00-00-01
- A source address taken from Specific Address register 1
- A type ID of 88-08 (MAC control frame)
- A pause opcode of 00-01
- A pause quantum register
- Fill of 00 to take the frame to minimum frame length
- Valid FCS

The pause quantum used in the generated frame will depend on the trigger source for the frame as follows:

- If bit 11 is written with a '1', the pause quantum will be taken from the Transmit Pause Quantum register. The Transmit Pause Quantum register resets to a value of 0xFFFF giving maximum pause quantum as default.
- If bit 12 is written with a '1', the pause quantum will be zero.

After transmission, a pause frame transmitted interrupt will be generated (bit 14 of the Interrupt Status register) and the only statistics register that will be incremented will be the Pause Frames Transmitted register.

Pause frames can also be transmitted by the MAC using normal frame transmission methods.

### 37.6.17 MAC PFC Priority-based Pause Frame Support

**Note:** Refer to the 802.1Qbb standard for a full description of priority-based pause operation.

The following table shows the start of a Priority-based Flow Control (PFC) pause frame.

**Table 37-15. Start of a PFC Pause Frame**

| Address        |         | Type<br>(Mac Control Frame) | Pause Opcode | Priority Enable Vector | Pause Time  |
|----------------|---------|-----------------------------|--------------|------------------------|-------------|
| Destination    | Source  |                             |              |                        |             |
| 0x0180C2000001 | 6 bytes | 0x8808                      | 0x1001       | 2 bytes                | 8 × 2 bytes |

The GMAC supports PFC priority-based pause transmission and reception. Before PFC pause frames can be received, bit 16 of the Network Control register must be set.

### 37.6.17.1 PFC Pause Frame Reception

The ability to receive and decode priority-based pause frames is enabled by setting bit 16 of the Network Control register. When this bit is set, the GMAC will match either classic 802.3 pause frames or PFC priority-based pause frames. Once a priority-based pause frame has been received and matched, then from that moment on the GMAC will only match on priority-based pause frames (this is an 802.1Qbb requirement, known as PFC negotiation). Once priority-based pause has been negotiated, any received 802.3x format pause frames will not be acted upon.

If a valid priority-based pause frame is received then the GMAC will decode the frame and determine which, if any, of the eight priorities require to be paused. Up to eight Pause Time registers are then updated with the eight pause times extracted from the frame regardless of whether a previous pause operation is active or not. An interrupt (either bit 12 or bit 13 of the Interrupt Status register) is triggered when a pause frame is received, but only if the interrupt has been enabled (bit 12 and bit 13 of the Interrupt Mask register). Pause frames received with non zero quantum are indicated through the interrupt bit 12 of the Interrupt Status register. Pause frames received with zero quantum are indicated on bit 13 of the Interrupt Status register. The loading of a new pause time only occurs when the GMAC is configured for full duplex operation. If the GMAC is configured for half duplex, the pause time counters will not be loaded, but the pause frame received interrupt will still be triggered. A valid pause frame is defined as having a destination address that matches either the address stored in Specific Address register 1 or if it matches the reserved address of 0x0180C2000001. It must also have the MAC control frame type ID of 0x8808 and have the pause opcode of 0x0101.

Pause frames that have frame check sequence (FCS) or other errors will be treated as invalid and will be discarded. Valid pause frames received will increment the Pause Frames Received Statistic register.

The Pause Time registers decrement every 512 bit times immediately following the PFC frame reception. For test purposes, the retry test bit can be set (bit 12 in the Network Configuration register) which causes the Pause Time register to decrement every GRXCK cycle once transmission has stopped.

The interrupt (bit 13 in the Interrupt Status register) is asserted whenever the Pause Time register decrements to zero (assuming it has been enabled by bit 13 in the Interrupt Mask register). This interrupt is also set when a zero quantum pause frame is received.

### 37.6.17.2 PFC Pause Frame Transmission

Automatic transmission of pause frames is supported through the transmit priority-based pause frame bit of the Network Control register. If bit 17 of the Network Control register is written with logic 1, a PFC pause frame will be transmitted providing full duplex is selected in the Network Configuration register and the transmit block is enabled in the Network Control register. When bit 17 of the Network Control register is set, the fields of the priority-based pause frame will be built using the values stored in the Transmit PFC Pause register.

Pause frame transmission will happen immediately if transmit is inactive or if transmit is active between the current frame and the next frame due to be transmitted.

Transmitted pause frames comprise the following:

- A destination address of 01-80-C2-00-00-01
- A source address taken from Specific Address register 1
- A type ID of 88-08 (MAC control frame)
- A pause opcode of 01-01
- A priority enable vector taken from Transmit PFC Pause register
- 8 pause quantum registers
- Fill of 00 to take the frame to minimum frame length
- Valid FCS

The pause quantum registers used in the generated frame will depend on the trigger source for the frame as follows:

- If bit 17 of the Network Control register is written with a one, then the priority enable vector of the priority-based pause frame will be set equal to the value stored in the Transmit PFC Pause register [7:0]. For each entry equal to zero in the Transmit PFC Pause register [15:8], the pause quantum field of the pause frame associated with that entry will be taken from the transmit pause quantum register. For each entry equal to one in the Transmit PFC Pause register [15:8], the pause quantum associated with that entry will be zero.
- The Transmit Pause Quantum register resets to a value of 0xFFFF giving maximum pause quantum as default.

After transmission, a pause frame transmitted interrupt will be generated (bit 14 of the Interrupt Status register) and the only statistics register that will be incremented will be the Pause Frames Transmitted register.

PFC Pause frames can also be transmitted by the MAC using normal frame transmission methods.

### 37.6.18 Energy Efficient Ethernet Support

#### Features

- Energy Efficient Ethernet according to IEEE 802.3az
- A system's transmit path can enter a low power mode if there is nothing to transmit.
- A PHY can detect whether its link partner's transmit path is in low power mode, and configure its own receive path to enter low power mode.
- Link remains up during lower power mode and no frames are dropped.
- Asymmetric, one direction can be in low power mode while the other is transmitting normally.
- LPI (Low Power Idle) signaling is used to control entry and exit to and from low power modes.  
**Note:** LPI signaling can only take place if both sides have indicated support for it through auto-negotiation.

#### Operation

- Low power control is done at the MII (reconciliation sublayer).
- As an architectural convenience in writing the 802.3az it is assumed that transmission is deferred by asserting carrier sense - in practice it will not be done this way. This system will know when it has nothing to transmit and only enter low power mode when it is not transmitting.
- LPI should not be requested unless the link has been up for at least one second.
- LPI is signaled on the MII transmit path by asserting 0x01 on txd with tx\_en low and tx\_er high.
- A PHY on seeing LPI requested on the MII will send the sleep signal before going quiet. After going quiet it will periodically emit refresh signals.
- The sleep, quiet and refresh periods are defined in 802.3az, Table 78-2.
- LPI mode ends by transmitting normal idle for the wake time. There is a default time for this but it can be adjusted in software using the Link Layer Discovery Protocol (LLDP) described in 802.3az, Clause 79.
- LPI is indicated at the receive side when sleep and refresh signaling has been detected.

### 37.6.19 802.1Qav Support - Credit-based Shaping

A credit-based shaping algorithm is available on the two highest priority queues and is defined in the standard 802.1Qav: Forwarding and Queuing Enhancements for Time-Sensitive Streams. This allows traffic on these queues to be limited and to allow other queues to transmit.

Traffic shaping is enabled via the CBS (Credit Based Shaping) Control register. This enables a counter which stores the amount of transmit 'credit', measured in bytes that a particular queue has. A queue may only transmit if it has non-negative credit. If a queue has data to send, but is held off from doing as another queue is transmitting, then credit will accumulate in the credit counter at the rate defined in the IdleSlope register (GMAC\_CBSISQx) for that queue.

**portTransmitRate** is the transmission rate, in bits per second, that the underlying MAC service that supports transmission through the Port provides. The value of this parameter is determined by the operation of the MAC. IdleSlope is the rate of change of increasing credit when waiting to transmit and must be less than the value of the portTransmitRate.

**IdleSlope** is the rate of change of credit when waiting to transmit and must be less than the value of the portTransmitRate.

The max value of IdleSlope (or sendSlope) is (portTransmitRate / bits\_per\_MII\_Clock).

In case of 100 Mbps, maximum IdleSlope = (100 Mbps / 4) = 0x17D7840.

When this queue is transmitting the credit counter is decremented at the rate of sendSlope which is defined as (portTransmitRate - IdleSlope). A queue can accumulate negative credit when transmitting which will hold off any other transfers from that queue until credit returns to a non-negative value. No transfers are halted when a queue's credit becomes negative; it will accumulate negative credit until the transfer completes.

The highest priority queue always has priority regardless of which queue has the most credit.

### 37.6.20 LPI Operation in the EMAC

It is best to use firmware to control LPI. LPI operation happens at the system level. Firmware gives maximum control and flexibility of operation. LPI operation is straightforward and firmware should be capable of responding within the required timeframes.

Autonegotiation:

1. Indicate EEE capability using next page autonegotiation.

For the transmit path:

1. If the link has been up for 1 second and there is nothing being transmitted, write to the TXLPIEN bit in the Network Control register.
2. Wake up by clearing the TXLPIEN bit in the Network Control register.

For the receive path:

1. Enable RXLPISBC bit in GMAC\_IER. The bit RXLPIS is set in Network Status Register triggering an interrupt.
2. Wait for an interrupt to indicate that LPI has been received.
3. Disable relevant parts of the receive path if desired.
4. The RXLPIS bit in Network Status Register gets cleared to indicate that regular idle has been received. This triggers an interrupt.
5. Re-enable the receive path.

### 37.6.21 PHY Interface

Different PHY interfaces are supported by the Ethernet MAC:

- MII
- RMII

The MII interface is provided for 10/100 operation and uses txd[3:0] and rxd[3:0]. The RMII interface is provided for 10/100 operation and uses txd[1:0] and rxd[1:0].

### 37.6.22 10/100 Operation

The 10/100 Mbps speed bit in the Network Configuration register is used to select between 10 Mbps and 100 Mbps.

### 37.6.23 Jumbo Frames

The jumbo frames enable bit in the Network Configuration register allows the GMAC, in its default configuration, to receive jumbo frames up to 10240 bytes in size. This operation does not form part of the IEEE 802.3 specification and is normally disabled. When jumbo frames are enabled, frames received with a frame size greater than 10240 bytes are discarded.

## 37.7 Programming Interface

### 37.7.1 Initialization

#### 37.7.1.1 Configuration

Initialization of the GMAC configuration (e.g., loop back mode, frequency ratios) must be done while the transmit and receive circuits are disabled. See the description of the Network Control register and Network Configuration register earlier in this document.

To change loop back mode, the following sequence of operations must be followed:

1. Write to Network Control register to disable transmit and receive circuits.
  2. Write to Network Control register to change loop back mode.
  3. Write to Network Control register to re-enable transmit or receive circuits.
- Note: These writes to the Network Control register cannot be combined in any way.

### 37.7.1.2 Receive Buffer List

Receive data is written to areas of data (i.e., buffers) in system memory. These buffers are listed in another data structure that also resides in main memory. This data structure (receive buffer queue) is a sequence of descriptor entries as defined in the table [Receive Buffer Descriptor Entry](#).

The Receive Buffer Queue Pointer register points to this data structure.

**Figure 37-3. Receive Buffer List**

To create the list of buffers:

1. Allocate a number (N) of buffers of X bytes in system memory, where X is the DMA buffer length programmed in the DMA Configuration register.
2. Allocate an area 8N bytes for the receive buffer descriptor list in system memory and create N entries in this list. Mark all entries in this list as owned by GMAC, i.e., bit 0 of word 0 set to 0.
3. Mark the last descriptor in the queue with the wrap bit (bit 1 in word 0 set to 1).
4. Write address of receive buffer descriptor list and control information to GMAC register receive buffer queue pointer
5. The receive circuits can then be enabled by writing to the address recognition registers and the Network Control register.

**Note:** The queue pointers must be initialized and point to USED descriptors for all queues including those not intended for use.

### 37.7.1.3 Transmit Buffer List

Transmit data is read from areas of data (the buffers) in system memory. These buffers are listed in another data structure that also resides in main memory. This data structure (Transmit Buffer Queue) is a sequence of descriptor entries as defined in the table [Transmit Buffer Descriptor Entry](#).

The Transmit Buffer Queue Pointer register points to this data structure.

To create this list of buffers:

1. Allocate a number (N) of buffers of between 1 and 2047 bytes of data to be transmitted in system memory. Up to 128 buffers per frame are allowed.
2. Allocate an area 8N bytes for the transmit buffer descriptor list in system memory and create N entries in this list. Mark all entries in this list as owned by GMAC, i.e., bit 31 of word 1 set to 0.
3. Mark the last descriptor in the queue with the wrap bit (bit 30 in word 1 set to 1).
4. Write address of transmit buffer descriptor list and control information to GMAC register transmit buffer queue pointer.
5. The transmit circuits can then be enabled by writing to the Network Control register.

**Note:** The queue pointers must be initialized and point to USED descriptors for all queues including those not intended for use.

### 37.7.1.4 Address Matching

The GMAC Hash register pair and the four Specific Address register pairs must be written with the required values. Each register pair comprises of a bottom register and top register, with the bottom register being written first. The address matching is disabled for a particular register pair after the bottom register has been written and re-enabled when the top register is written. Each register pair may be written at any time, regardless of whether the receive circuits are enabled or disabled.

As an example, to set Specific Address register 1 to recognize destination address 21:43:65:87:A9:CB, the following values are written to Specific Address register 1 bottom and Specific Address register 1 top:

- Specific Address register 1 bottom bits 31:0 (0x98): 0x8765\_4321.
- Specific Address register 1 top bits 31:0 (0x9C): 0x0000\_CBA9.

**Note:** The address matching is the first level of filtering. If there is a match, the screeners are the next level of filtering for routing the data to the appropriate queue. See [Priority Queueing in the DMA](#) for more details.

### 37.7.1.5 PHY Maintenance

The PHY Maintenance register is implemented as a shift register. Writing to the register starts a shift operation which is signalled as complete when bit two is set in the Network Status register (about 2000 MCK cycles later when bits 18:16 are set to 010 in the Network Configuration register). An interrupt is generated as this bit is set.

During this time, the MSB of the register is output on the MDIO pin and the LSB updated from the MDIO pin with each Management Data Clock (MDC) cycle. This causes the transmission of a PHY management frame on MDIO. See section 22.2.4.5 of the IEEE 802.3 standard.

Reading during the shift operation will return the current contents of the shift register. At the end of the management operation the bits will have shifted back to their original locations. For a read operation the data bits are updated with data read from the PHY. It is important to write the correct values to the register to ensure a valid PHY management frame is produced.

The Management Data Clock (MDC) should not toggle faster than 2.5 MHz (minimum period of 400 ns), as defined by the IEEE 802.3 standard. MDC is generated by dividing down MCK. Three bits in the Network Configuration register determine by how much MCK should be divided to produce MDC.

### 37.7.1.6 Interrupts

There are 18 interrupt conditions that are detected within the GMAC. The conditions are ORed to make multiple interrupts. Depending on the overall system design this may be passed through a further level of interrupt collection (interrupt controller). On receipt of the interrupt signal, the CPU enters the interrupt handler. Refer to the device interrupt controller documentation to identify that it is the GMAC that is generating the interrupt. To ascertain which interrupt, read the Interrupt Status register. Note that in the default configuration this register will clear itself after being read, though this may be configured to be write-one-to-clear if desired.

At reset all interrupts are disabled. To enable an interrupt, write to Interrupt Enable register with the pertinent interrupt bit set to 1. To disable an interrupt, write to Interrupt Disable register with the pertinent interrupt bit set to 1. To check whether an interrupt is enabled or disabled, read Interrupt Mask register. If the bit is set to 1, the interrupt is disabled.

### 37.7.1.7 Transmitting Frames

The procedure to set up a frame for transmission is the following:

1. Enable transmit in the Network Control register.
2. Allocate an area of system memory for transmit data. This does not have to be contiguous, varying byte lengths can be used if they conclude on byte borders.
3. Set-up the transmit buffer list by writing buffer addresses to word zero of the transmit buffer descriptor entries and control and length to word one.
4. Write data for transmission into the buffers pointed to by the descriptors.
5. Write the address of the first buffer descriptor to transmit buffer descriptor queue pointer.
6. Enable appropriate interrupts.
7. Write to the transmit start bit (TSTART) in the Network Control register.

### 37.7.1.8 Receiving Frames

When a frame is received and the receive circuits are enabled, the GMAC checks the address and, in the following cases, the frame is written to system memory:

- If it matches one of the four Specific Address registers.
- If it matches one of the four type ID registers.
- If it matches the hash address function.
- If it is a broadcast address (0xFFFFFFFF) and broadcasts are allowed.
- If the GMAC is configured to “copy all frames”.

The register receive buffer queue pointer points to the next entry in the receive buffer descriptor list and the GMAC uses this as the address in system memory to write the frame to.

Once the frame has been completely and successfully received and written to system memory, the GMAC then updates the receive buffer descriptor entry (see [Receive Buffer Descriptor Entry](#)) with the reason for the address match and marks the area as being owned by software. Once this is complete, a receive complete interrupt is set. Software is then responsible for copying the data to the application area and releasing the buffer (by writing the ownership bit back to 0).

If the GMAC is unable to write the data at a rate to match the incoming frame, then a receive overrun interrupt is set. If there is no receive buffer available, i.e., the next buffer is still owned by software, a receive buffer not available interrupt is set. If the frame is not successfully received, a statistics register is incremented and the frame is discarded without informing software.

### 37.7.2 Statistics Registers

Statistics registers are described in the User Interface beginning with [GMAC Octets Transmitted Low Register](#) and ending with [GMAC UDP Checksum Errors Register](#).

The statistics register block begins at 0x100 and runs to 0x1B0, and comprises the registers listed below.

|  |   |
|--|---|
| Octets Transmitted Low Register                    | Broadcast Frames Received Register            |
| Octets Transmitted High Register                   | Multicast Frames Received Register            |
| Frames Transmitted Register                        | Pause Frames Received Register                |
| Broadcast Frames Transmitted Register              | 64 Byte Frames Received Register              |
| Multicast Frames Transmitted Register              | 65 to 127 Byte Frames Received Register       |
| Pause Frames Transmitted Register                  | 128 to 255 Byte Frames Received Register      |
| 64 Byte Frames Transmitted Register                | 256 to 511 Byte Frames Received Register      |
| 65 to 127 Byte Frames Transmitted Register         | 512 to 1023 Byte Frames Received Register     |
| 128 to 255 Byte Frames Transmitted Register        | 1024 to 1518 Byte Frames Received Register    |
| 256 to 511 Byte Frames Transmitted Register        | 1519 to Maximum Byte Frames Received Register |
| 512 to 1023 Byte Frames Transmitted Register       | Undersize Frames Received Register            |
| 1024 to 1518 Byte Frames Transmitted Register      | Oversize Frames Received Register             |
| Greater Than 1518 Byte Frames Transmitted Register | Jabbers Received Register                     |
| Transmit Underruns Register                        | Frame Check Sequence Errors Register          |
| Single Collision Frames Register                   | Length Field Frame Errors Register            |
| Multiple Collision Frames Register                 | Receive Symbol Errors Register                |
| Excessive Collisions Register                      | Alignment Errors Register                     |
| Late Collisions Register                           | Receive Resource Errors Register              |
| Deferred Transmission Frames Register              | Receive Overrun Register                      |
| Carrier Sense Errors Register                      | IP Header Checksum Errors Register            |
| Octets Received Low Register                       | TCP Checksum Errors Register                  |

# SAM E70/S70/V70/V71

## GMAC - Ethernet MAC

---

---

|                               |                              |
|-------------------------------|------------------------------|
| Octets Received High Register | UDP Checksum Errors Register |
| Frames Received Register      |                              |

These registers reset to zero on a read and stick at all ones when they count to their maximum value. They should be read frequently enough to prevent loss of data.

The receive statistics registers are only incremented when the receive enable bit (RXEN) is set in the Network Control register.

Once a statistics register has been read, it is automatically cleared. When reading the Octets Transmitted and Octets Received registers, bits 31:0 should be read prior to bits 47:32 to ensure reliable operation.

### 37.8 Register Summary

| Offset | Name       | Bit Pos. | 7           | 6         | 5         | 4          | 3         | 2          | 1      | 0      |  |
|--------|------------|----------|-------------|-----------|-----------|------------|-----------|------------|--------|--------|--|
| 0x00   | GMAC_NCR   | 7:0      | WESTAT      | INCSTAT   | CLRSTAT   | MPE        | TXEN      | RXEN       | LBL    |        |  |
|        |            | 15:8     | SRTSM       |           |           | TXZQPF     | TXPF      | THALT      | TSTART | BP     |  |

| Access |     | R/W    | R/W     | R/W     | R/W    | R/W  | R/W   | R/W    |        |  |
| Reset  |     | 0      | 0       | 0       | 0      | 0    | 0     | 0      |        |  |

**Bit 18 – FNP** Flush Next Packet

Writing a '1' to this bit will flush the next packet from the external RX DPRAM. Flushing the next packet will only take effect if the DMA is not currently writing a packet already stored in the DPRAM to memory.

**Bit 17 – TXPBPF** Transmit PFC Priority-based Pause Frame

Takes the values stored in the Transmit PFC Pause Register.

**Bit 16 – ENPBPR** Enable PFC Priority-based Pause Reception

Writing a '1' to this bit enables PFC Priority Based Pause Reception capabilities, enabling PFC negotiation and recognition of priority-based pause frames.

| Value | Description                                     |
|-------|---|
| 0     | Normal operation                                |
| 1     | PFC Priority-based Pause frames are recognized. |

**Bit 15 – SRTSM** Store Receive Time Stamp to Memory

Writing a '1' to this bit causes the CRC of every received frame to be replaced with the value of the nanoseconds field of the 1588 timer that was captured as the receive frame passed the message time stamp point.

Note that bit RFCS in register GMAC\_NCFGR may not be set to 1 when the timer should be captured.

| Value | Description   |
|-------|---|
| 0     | Normal operation  |
| 1     | All received frames' CRC is replaced with a time stamp. |

**Bit 12 – TXZQPF** Transmit Zero Quantum Pause Frame

Writing a '1' to this bit causes a pause frame with zero quantum to be transmitted.

Writing a '0' to this bit has no effect.

**Bit 11 – TXPF** Transmit Pause Frame

Writing one to this bit causes a pause frame to be transmitted.

Writing a '0' to this bit has no effect.

**Bit 10 – THALT** Transmit Halt

Writing a '1' to this bit halts transmission as soon as any ongoing frame transmission ends.  
Writing a '0' to this bit has no effect.

**Bit 9 – TSTART** Start Transmission

Writing a '1' to this bit starts transmission.  
Writing a '0' to this bit has no effect.

**Bit 8 – BP** Back Pressure

In 10M or 100M half duplex mode, writing a '1' to this bit forces collisions on all received frames. Ignored in gigabit half duplex mode.

| Value | Description   |
|-------|---|
| 0     | Frame collisions are not forced.                              |
| 1     | Frame collisions are forced in 10M and 100M half duplex mode. |

**Bit 7 – WESTAT** Write Enable for Statistics Registers

Writing a '1' to this bit makes the statistics registers writable for functional test purposes.

| Value | Description                               |
|-------|---|
| 0     | Statistics Registers are write-protected. |
| 1     | Statistics Registers are write-enabled.   |

**Bit 6 – INCSTAT** Increment Statistics Registers

Writing a '1' to this bit increments all Statistics Registers by one for test purposes.  
Writing a '0' to this bit has no effect.  
This bit will always read '0'.

**Bit 5 – CLRSTAT** Clear Statistics Registers

Writing a '1' to this bit clears the Statistics Registers.  
Writing a '0' to this bit has no effect.  
This bit will always read '0'.

**Bit 4 – MPE** Management Port Enable

Writing a '1' to this bit enables the Management Port.  
Writing a '0' to this bit disables the Management Port, and forces MDIO to high impedance state and MDC to low impedance.

| Value | Description                  |
|-------|------------------------------|
| 0     | Management Port is disabled. |
| 1     | Management Port is enabled.  |

**Bit 3 – TXEN** Transmit Enable

Writing a '1' to this bit enables the GMAC transmitter to send data.  
Writing a '0' to this bit stops transmission immediately, the transmit pipeline and control registers is cleared, and the Transmit Queue Pointer Register will be set to point to the start of the transmit descriptor list.

| Value | Description           |
|-------|-----------------------|
| 0     | Transmit is disabled. |
| 1     | Transmit is enabled.  |

**Bit 2 – RXEN** Receive Enable

Writing a '1' to this bit enables the GMAC to receive data.  
Writing a '0' to this bit stops frame reception immediately, and the receive pipeline is cleared. The Receive Queue Pointer Register is not affected.

| Value | Description          |
|-------|----------------------|
| 0     | Receive is disabled. |
| 1     | Receive is enabled.  |

**Bit 1 – LBL** Loop Back Local

Writing '1' to this bit connects GTX to GRX, GTXEN to GRXDV, and forces full duplex mode.

# SAM E70/S70/V70/V71

## GMAC - Ethernet MAC

GRXCK and GTXCK may malfunction as the GMAC is switched into and out of internal loop back. It is important that receive and transmit circuits have already been disabled when making the switch into and out of internal loop back.

| Value | Description                  |
|-------|------------------------------|
| 0     | Loop back local is disabled. |
| 1     | Loop back local is enabled.  |

| Reset  |     | 0           | 0        | 0    | 0      | 0        | 0      | 0     | 0      |       |

**Bit 30 – IRXER** Ignore IPG GRXER

When this bit is written to '1', the Receive Error signal (GRXER) has no effect on the GMAC operation when Receive Data Valid signal (GRXDV) is low.

**Note:** Write this bit to '1' when using the RMGII wrapper in half-duplex mode.

**Bit 29 – RXBP** Receive Bad Preamble

When written to '1', frames with non-standard preamble are not rejected.

**Bit 28 – IPGSEN** IP Stretch Enable

Writing a '1' to this bit allows the transmit IPG to increase above 96 bit times, depending on the previous frame length using the IPG Stretch Register.

**Bit 26 – IRXFCS** Ignore RX FCS

For normal operation this bit must be written to zero.

When this bit is written to '1', frames with FCS/CRC errors will not be rejected. FCS error statistics will still be collected for frames with bad FCS, and FCS status will be recorded in the DMA descriptor of the frame.

**Bit 25 – EFRHD** Enable Frames Received in half-duplex

Writing a '1' to this bit enables frames to be received in half-duplex mode while transmitting.

**Bit 24 – RXCOEN** Receive Checksum Offload Enable

Writing a '1' to this bit enables the receive checksum engine, and frames with bad IP, TCP or UDP checksums are discarded.

**Bit 23 – DCPF** Disable Copy of Pause Frames

Writing a '1' to this bit prevents valid pause frames from being copied to memory. Pause frames are not copied regardless of the state of the Copy All Frames (CAF) bit, whether a hash match is found or whether a type ID match is identified.

If a destination address match is found, the pause frame will be copied to memory. Note that valid pause frames received will still increment pause statistics and pause the transmission of frames, as required.

### Bits 22:21 – DBW[1:0] Data Bus Width

Should always be written to '0'. The default value for this register is 64 bits. Should always be written to '1'.

| Value | Name  | Description           |
|-------|-------|-----------------------|
| 0     | DBW32 | 32-bit data bus width |
| 1     | DBW64 | 64-bit data bus width |

### Bits 20:18 – CLK[2:0] MDC Clock Division

These bits must be set according to MCK speed, and determine the number MCK will be divided by to generate Management Data Clock (MDC). For conformance with the 802.3 specification, MDC must not exceed 2.5MHz.

**Note:** MDC is only active during MDIO read and write operations.

| Value | Name   | Description                          |
|-------|--------|--------------------------------------|
| 0     | MCK_8  | MCK divided by 8 (MCK up to 20MHz)   |
| 1     | MCK_16 | MCK divided by 16 (MCK up to 40MHz)  |
| 2     | MCK_32 | MCK divided by 32 (MCK up to 80MHz)  |
| 3     | MCK_48 | MCK divided by 48 (MCK up to 120MHz) |
| 4     | MCK_64 | MCK divided by 64 (MCK up to 160MHz) |
| 5     | MCK_96 | MCK divided by 96 (MCK up to 240MHz) |

### Bit 17 – RFCS Remove FCS

Writing this bit to '1' will cause received frames to be written to memory without their frame check sequence (last 4 bytes). The indicated frame length will be reduced by four bytes in this mode.

### Bit 16 – LFERD Length Field Error Frame Discard

Writing a '1' to this bit discards frames with a measured length shorter than the extracted length field (as indicated by bytes 13 and 14 in a non-VLAN tagged frame). This only applies to frames with a length field less than 0x0600.

### Bits 15:14 – RXBUFO[1:0] Receive Buffer Offset

These bits determine the number of bytes by which the received data is offset from the start of the receive buffer.

### Bit 13 – PEN Pause Enable

When written to '1', transmission will pause if a non-zero 802.3 classic pause frame is received and PFC has not been negotiated.

### Bit 12 – RTY Retry Test

This bit must be written to '0' for normal operation.

When writing a '1' to this bit, the back-off between collisions will always be one slot time. This setting helps testing the too many retries condition. This setting is also useful for pause frame tests by reducing the pause counter's decrement time from "512 bit times" to "every GRXCK cycle".

### Bit 10 – GBE Gigabit Mode Enable

Writing a '1' configures the GMAC for 1000 Mbps operation.

| Value | Description                             |
|-------|---|
| 0     | 10/100 operation using MII interface.   |
| 1     | Gigabit operation using GMII interface. |

### Bit 8 – MAXFS 1536 Maximum Frame Size

Writing a '1' to this bit increases the maximum accepted frame size to 1536 bytes in length. When written to '0', any frame above 1518 bytes in length is rejected.

### Bit 7 – UNIHEN Unicast Hash Enable

When writing a '1' to this bit, unicast frames will be accepted when the 6-bit hash function of the destination address points to a bit that is set in the Hash Register.

Writing a '0' to this bit disables unicast hashing.

**Bit 6 – MTIHEN** Multicast Hash Enable

When writing a '1' to this bit, multicast frames will be accepted when the 6-bit hash function of the destination address points to a bit that is set in the Hash Register.  
Writing a '0' to this bit disables multicast hashing.

**Bit 5 – NBC** No Broadcast

Writing a '1' to this bit will reject frames addressed to the broadcast address 0xFFFFFFFF (all '1').  
Writing a '0' to this bit allows broadcasting to 0xFFFFFFFF.

**Bit 4 – CAF** Copy All Frames

When writing a '1' to this bit, all valid frames will be accepted.

**Bit 3 – JFRAME** Jumbo Frame Size

Writing a '1' to this bit enables jumbo frames of up to 10240 bytes to be accepted. The default length is 10240 bytes.

**Bit 2 – DNVLAN** Discard Non-VLAN Frames

Writing a '1' to this bit allows only VLAN-tagged frames to pass to the address matching logic.  
Writing a '0' to this bit allows both VLAN\_tagged and untagged frames to pass to the address matching logic.

**Bit 1 – FD** Full Duplex

Writing a '1' enables full duplex operation, so the transmit block ignores the state of collision and carrier sense and allows receive while transmitting.  
Writing a '0' disables full duplex operation.

**Bit 0 – SPD** Speed

Writing a '1' selects 100Mbps operation.  
Writing a '0' to this bit selects 10Mbps operation.

### 37.8.3 GMAC Network Status Register

**Name:** GMAC\_NSR  
**Offset:** 0x008  
**Reset:** 0x000001X0  
**Property:** Read-only

**Bit 2 – IDLE** PHY Management Logic Idle  
 The PHY management logic is idle (i.e., has completed).

**Bit 1 – MDIO** MDIO Input Status  
 Returns status of the GMDIO pin.

**37.8.4 GMAC User Register**

**Name:** GMAC\_UR  
**Offset:** 0x00C  
**Reset:** 0x00000000  
**Property:** -

**Bit 0 – MII Reduced MII Mode**

| Value | Description           |
|-------|-----------------------|
| 0     | RMII mode is selected |
| 1     | MII mode is selected  |

### 37.8.5 GMAC DMA Configuration Register

**Name:** GMAC\_DCFGR  
**Offset:** 0x010  
**Reset:** 0x00020704  
**Property:** Read/Write

|        |           |     |      |        |            |        |     |            |  |
|--------|-----------|-----|------|--------|------------|--------|-----|------------|--|
| Bit    | 31        | 30  | 29   | 28     | 27         | 26     | 25  | 24         |  |
|        |           |     |      |        |            |        |     | DDRP       |  |
| Access |           |     |      |        |            |        |     | R/W        |  |
| Reset  |           |     |      |        |            |        |     | 0          |  |
|        |           |     |      |        |            |        |     |            |  |

| Bit    | 7         | 6   | 5    | 4      | 3          | 2      | 1   | 0          |  |
|        | ESPA      |     | ESMA |        | FBLDO[4:0] |        |     |            |  |
| Access | R/W       |     | R/W  |        | R/W        |        | R/W |            |  |
| Reset  | 0         |     | 0    |        | 0          |        | 0   |            |  |

#### Bit 24 – DDRP DMA Discard Receive Packets

A write to this bit is ignored if the DMA is not configured in the packet buffer full store and forward mode.

| Value | Description   |
|-------|---|
| 0     | Received packets are stored in the SRAM based packet buffer until next AHB buffer resource becomes available.         |
| 1     | Receive packets from the receiver packet buffer memory are automatically discarded when no AHB resource is available. |

#### Bits 23:16 – DRBS[7:0] DMA Receive Buffer Size

The values defined by these bits determines the size of buffer to use in main AHB system memory when writing received data.

The value is defined in multiples of 64 bytes, for example:

- 0x02: 128 bytes
- 0x18: 1536 bytes (1 × max length frame/buffer)
- 0xA0: 10240 bytes (1 × 10K jumbo frame/buffer)

Do not write 0x00 to this bit field.

#### Bit 11 – TXCOEN Transmitter Checksum Generation Offload Enable

Transmitter IP, TCP and UDP checksum generation offload enable.

| Value | Description  |
|-------|--|
| 0     | Frame data is unaffected.  |
| 1     | The transmitter checksum generation engine calculates and substitutes checksums for transmit frames. |

**Bit 10 – TXPBMS** Transmitter Packet Buffer Memory Size Select

When written to zero, the amount of memory used for the transmit packet buffer is reduced by 50%. This reduces the amount of memory used by the GMAC.

It is important to write this bit to '1' if the full configured physical memory is available. The value in parentheses represents the size that would result for the default maximum configured memory size of 4KBytes.

| Value | Description                                       |
|-------|---|
| 0     | Top address bits not used. (2KByte used.)         |
| 1     | Full configured addressable space (4KBytes) used. |

**Bits 9:8 – RXBMS[1:0]** Receiver Packet Buffer Memory Size Select

The default receive packet buffer size is FULL= Kbytes. The table below shows how to configure this memory to FULL, HALF, QUARTER or EIGHTH of the default size.

| Value | Name    | Description           |
|-------|---------|-----------------------|
| 0     | EIGHTH  | /8 Kbyte Memory Size  |
| 1     | QUARTER | /4 Kbytes Memory Size |
| 2     | HALF    | /2 Kbytes Memory Size |
| 3     | FULL    | Kbytes Memory Size    |

**Bit 7 – ESPA** Endian Swap Mode Enable for Packet Data Accesses

| Value | Description                                    |
|-------|--|
| 0     | Little endian mode for AHB transfers selected. |
| 1     | Big endian mode for AHB transfers selected.    |

**Bit 6 – ESMA** Endian Swap Mode Enable for Management Descriptor Accesses

| Value | Description                                    |
|-------|--|
| 0     | Little endian mode for AHB transfers selected. |
| 1     | Big endian mode for AHB transfers selected.    |

**Bits 4:0 – FBLDO[4:0]** Fixed Burst Length for DMA Data Operations

Selects the burst length to attempt to use on the AHB when transferring frame data. Not used for DMA management operations and only used where space and data size allow. Otherwise SINGLE type AHB transfers are used.

One-hot priority encoding enforced automatically on register writes as follows. 'x' represents don't care.

| Value | Name   | Description                                      |
|-------|--------|--|
| 0     | -      | Reserved   |
| 1     | SINGLE | 00001: Always use SINGLE AHB bursts              |
| 2     | -      | Reserved   |
| 4     | INCR4  | 001xx: Attempt to use INCR4 AHB bursts (Default) |
| 8     | INCR8  | 01xxx: Attempt to use INCR8 AHB bursts           |
| 16    | INCR16 | 1xxxx: Attempt to use INCR16 AHB bursts          |

### 37.8.6 GMAC Transmit Status Register

**Name:** GMAC\_TSR  
**Offset:** 0x014  
**Reset:** 0x00000000  
**Property:** -

|        |     |     |     |        |     |      |     |     |       |
|--------|-----|-----|-----|--------|-----|------|-----|-----|-------|
|        | Bit | 31  | 30  | 29     | 28  | 27   | 26  | 25  | 24    |
|        |     |     |     |        |     |      |     |     |       |
| Access |     |     |     |        |     |      |     |     |       |
| Reset  |     |     |     |        |     |      |     |     |       |
|        |     |     |     |        |     |      |     |     |       |
|        | Bit | 23  | 22  | 21     | 20  | 19   | 18  | 17  | 16    |
|        |     |     |     |        |     |      |     |     |       |
| Access |     |     |     |        |     |      |     |     |       |
| Reset  |     |     |     |        |     |      |     |     |       |
|        |     |     |     |        |     |      |     |     |       |
|        | Bit | 15  | 14  | 13     | 12  | 11   | 10  | 9   | 8     |
|        |     |     |     |        |     |      |     |     | HRESP |
| Access |     |     |     |        |     |      |     |     | R/W   |
| Reset  |     |     |     |        |     |      |     |     | 0     |
|        |     |     |     |        |     |      |     |     |       |
|        | Bit | 7   | 6   | 5      | 4   | 3    | 2   | 1   | 0     |
|        |     | LCO | UND | TXCOMP | TFC | TXGO | RLE | COL | UBR   |
| Access |     | R/W | R/W | R/W    | R/W | R/W  | R/W | R/W | R/W   |
| Reset  |     | 0   | 0   | 0      | 0   | 0    | 0   | 0   | 0     |

**Bit 8 – HRESP** HRESP Not OK

Set when the DMA block sees HRESP not OK.  
 This bit is cleared by writing a '1' to it.

**Bit 7 – LCO** Late Collision Occurred

This bit is set when a late collision occurred gigabit mode, where a retry is not attempted.  
 This bit is cleared by writing a '1' to it.

**Bit 6 – UND** Transmit Underrun

This bit is set if the transmitter was forced to terminate the transmission of a frame due to further data being unavailable.  
 This bit is also set if a transmitter status write back has not completed when another status write back is attempted.  
 When using the DMA interface configured for internal FIFO mode, this bit is also set when the transmit DMA has written the SOP data into the FIFO and either the AHB bus was not granted in time for further data, or an AHB not OK response was returned, or a used bit was read.  
 This bit is cleared by writing a '1' to it.

**Bit 5 – TXCOMP** Transmit Complete

Set when a frame has been transmitted.  
 This bit is cleared by writing a '1' to it.

**Bit 4 – TFC** Transmit Frame Corruption Due to AHB Error

This bit is set when an error occurs during reading transmit frame from the AHB. Error causes include HRESP errors and buffers exhausted mid frame. (If the buffers run out during transmission of a frame then transmission stops, FCS shall be bad and GTXER asserted).  
 In DMA packet buffer mode, this bit is also set if a single frame is too large for the configured packet buffer memory size.  
 This bit is cleared by writing a '1' to it.

**Bit 3 – TXGO** Transmit Go

This bit is '1' when transmit is active. When using the DMA interface this bit represents the TXGO variable as specified in the transmit buffer description.

**Bit 2 – RLE** Retry Limit Exceeded

This bit is cleared by writing a '1' to it.

**Bit 1 – COL** Collision Occurred

When operating in 10/100Mbps mode, this bit is set by the assertion of either a collision or a late collision.

When operating in Gb mode, this bit is set by the assertion of a collision, but not of a late collision.

This bit is cleared by writing a '1' to it.

**Bit 0 – UBR** Used Bit Read

This bit is set when a transmit buffer descriptor is read with its used bit set.

This bit is cleared by writing a '1' to it.

### 37.8.7 GMAC Receive Buffer Queue Base Address Register

**Name:** GMAC\_RBQB  
**Offset:** 0x018  
**Reset:** 0x00000000  
**Property:** Read/Write

This register holds the start address of the receive buffer queue (receive buffers descriptor list). The receive buffer queue base address must be initialized before receive is enabled through bit 2 of the Network Control Register. Once reception is enabled, any write to the Receive Buffer Queue Base Address Register is ignored. Reading this register returns the location of the descriptor currently being accessed. This value increments as buffers are used. Software should not use this register for determining where to remove received frames from the queue as it constantly changes as new frames are received. Software should instead work its way through the buffer descriptor queue checking the “used” bits.

In terms of AMBA AHB operation, the descriptors are read from memory using a single 32-bit AHB access. When the datapath is configured at 64 bits, the descriptors should be aligned at 64-bit boundaries and each pair of 32-bit descriptors is written to by using a single AHB access. The descriptors should be aligned at 32-bit boundaries and the descriptors are written to using two individual non sequential accesses for 32-bit datapaths.

**Bits 31:2 – ADDR[29:0]** Receive Buffer Queue Base Address  
 Written with the address of the start of the receive queue.

### 37.8.8 GMAC Transmit Buffer Queue Base Address Register

**Name:** GMAC\_TBQB  
**Offset:** 0x01C  
**Reset:** 0x00000000  
**Property:** -

This register holds the start address of the transmit buffer queue (transmit buffers descriptor list). The Transmit Buffer Queue Base Address Register must be initialized before transmit is started through bit 9 of the Network Control Register. Once transmission has started, any write to the Transmit Buffer Queue Base Address Register is illegal and therefore ignored.

Note that due to clock boundary synchronization, it takes a maximum of four MCK cycles from the writing of the transmit start bit before the transmitter is active. Writing to the Transmit Buffer Queue Base Address Register during this time may produce unpredictable results.

Reading this register returns the location of the descriptor currently being accessed. Since the DMA handles two frames at once, this may not necessarily be pointing to the current frame being transmitted.

In terms of AMBA AHB operation, the descriptors are written to memory using a single 32-bit AHB access. When the datapath is configured at 64 bits, the descriptors should be aligned at 64-bit boundaries and each pair of 32-bit descriptors is read from memory using a single AHB access. The descriptors should be aligned at 32-bit boundaries and the descriptors are read from memory using two individual non sequential accesses for 32-bit datapaths.

**Bits 31:2 – ADDR[29:0]** Transmit Buffer Queue Base Address  
 Written with the address of the start of the transmit queue.

### 37.8.9 GMAC Receive Status Register

**Name:** GMAC\_RSR  
**Offset:** 0x020  
**Reset:** 0x00000000  
**Property:** -

This register, when read, provides receive status details. Once read, individual bits may be cleared by writing a '1' to them. It is not possible to set a bit to '1' by writing to this register.

**Bit 3 – HNO** HRESP Not OK

This bit is set when the DMA block sees HRESP not OK.  
 This bit is cleared by writing a '1' to it.

**Bit 2 – RXOVR** Receive Overrun

This bit is set if RX FIFO is not able to store the receive frame due to a FIFO overflow, or if the receive status was not taken at the end of the frame. This bit is also set if the packet buffer overflows. The buffer will be recovered if an overrun occurs.  
 This bit is cleared by writing a '1' to it.

**Bit 1 – REC** Frame Received

This bit is set to when one or more frames have been received and placed in memory.  
 This bit is cleared by writing a '1' to it.

**Bit 0 – BNA** Buffer Not Available

When this bit is set, an attempt was made to get a new buffer and the pointer indicated that it was owned by the processor. The DMA will re-read the pointer each time an end of frame is received until a valid pointer is found. This bit is set following each descriptor read attempt that fails, even if consecutive pointers are unsuccessful and software has in the mean time cleared the status flag.  
 This bit is cleared by writing a '1' to it.

### 37.8.10 GMAC Interrupt Status Register

**Name:** GMAC\_ISR  
**Offset:** 0x024  
**Reset:** 0x00000000  
**Property:** Read-only

This register indicates the source of the interrupt. An interrupt source must be enabled in the mask register first so the corresponding bits of this register will be set and the GMAC interrupt signal will be asserted in the system.

|        |     |        |        |           |       |          |       |        |        |
|--------|-----|--------|--------|-----------|-------|----------|-------|--------|--------|

| Access |     | R      | R      | R         | R     | R        | R     | R      | R      |
| Reset  |     | 0      | 0      | 0         | 0     | 0        | 0     | 0      | 0      |

**Bit 29 – TSUTIMCMP** TSU Timer Comparison  
 Indicates when TSU timer count value is equal to programmed value.  
 Cleared on read.

**Bit 28 – WOL** Wake On LAN  
 WOL interrupt. Indicates a WOL message has been received.

**Bit 27 – RXLPISBC** Receive LPI indication Status Bit Change  
 Receive LPI indication status bit change.  
 Cleared on read.

**Bit 26 – SRI** TSU Seconds Register Increment  
 Indicates the register has incremented.  
 Cleared on read.

**Bit 25 – PDRSFT** PDelay Response Frame Transmitted  
 Indicates a PTP pdelay\_resp frame has been transmitted.  
 Cleared on read.

**Bit 24 – PDRQFT** PDelay Request Frame Transmitted  
 Indicates a PTP pdelay\_req frame has been transmitted.  
 Cleared on read.

**Bit 23 – PDRSFR** PDelay Response Frame Received  
 Indicates a PTP pdelay\_resp frame has been received.  
 Cleared on read.

**Bit 22 – PDRQFR** PDelay Request Frame Received

Indicates a PTP pdelay\_req frame has been received.  
Cleared on read.

**Bit 21 – SFT** PTP Sync Frame Transmitted

Indicates a PTP sync frame has been transmitted.  
Cleared on read.

**Bit 20 – DRQFT** PTP Delay Request Frame Transmitted

Indicates a PTP delay\_req frame has been transmitted.  
Cleared on read.

**Bit 19 – SFR** PTP Sync Frame Received

Indicates a PTP sync frame has been received.  
Cleared on read.

**Bit 18 – DRQFR** PTP Delay Request Frame Received

Indicates a PTP delay\_req frame has been received.  
Cleared on read.

**Bit 14 – PFTR** Pause Frame Transmitted

Indicates a pause frame has been successfully transmitted after being initiated from the Network Control Register.  
Cleared on read.

**Bit 13 – PTZ** Pause Time Zero

Set when either the Pause Time Register at address 0x38 decrements to zero, or when a valid pause frame is received with a zero pause quantum field.  
Cleared on read.

**Bit 12 – PFNZ** Pause Frame with Non-zero Pause Quantum Received

Indicates a valid pause has been received that has a non-zero pause quantum field.  
Cleared on read.

**Bit 11 – HRESP** HRESP Not OK

Set when the DMA block sees HRESP not OK.  
Cleared on read.

**Bit 10 – ROVR** Receive Overrun

Set when the receive overrun status bit is set.  
Cleared on read.

**Bit 7 – TCOMP** Transmit Complete

Set when a frame has been transmitted.  
Cleared on read.

**Bit 6 – TFC** Transmit Frame Corruption Due to AHB Error

Transmit frame corruption due to AHB error. Set if an error occurs during reading a transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame.

**Bit 5 – RLEX** Retry Limit Exceeded or Late Collision

Retry Limit Exceeded or Late Collision Transmit error. Late Collision will only cause this status bit to be set in gigabit mode, as a retry is not attempted.  
Cleared on read.

**Bit 4 – TUR** Transmit Underrun

This interrupt is set if the transmitter was forced to terminate an ongoing frame transmission due to further data being unavailable.

This interrupt is also set if a transmitter status write back has not completed when another status write back is attempted.

This interrupt is also set when the transmit DMA has written the SOP data into the FIFO and either the AHB bus was not granted in time for further data, or because an AHB not OK response was returned, or because the used bit was read.

**Bit 3 – TXUBR** TX Used Bit Read

Set when a transmit buffer descriptor is read with its used bit set.  
Cleared on read.

**Bit 2 – RXUBR** RX Used Bit Read

Set when a receive buffer descriptor is read with its used bit set.  
Cleared on read.

**Bit 1 – RCOMP** Receive Complete

A frame has been stored in memory.  
Cleared on read.

**Bit 0 – MFS** Management Frame Sent

The PHY Maintenance Register has completed its operation.  
Cleared on read.

### 37.8.11 GMAC Interrupt Enable Register

**Name:** GMAC\_IER  
**Offset:** 0x028  
**Reset:** –  
**Property:** Write-only

This register is write-only and will always return zero.

The following values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |        |        |           |       |          |       |        |        |

### 37.8.12 GMAC Interrupt Disable Register

**Name:** GMAC\_IDR  
**Offset:** 0x02C  
**Reset:** –  
**Property:** Write-only

This register is write-only and will always return zero.

The following values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

|        |     |        |        |           |       |          |       |        |        |

### 37.8.13 GMAC Interrupt Mask Register

**Name:** GMAC\_IMR  
**Offset:** 0x030  
**Reset:** 0x07FFFFFFF  
**Property:** Read/Write

This register is a read-only register indicating which interrupts are masked. All bits are set at Reset and can be reset individually by writing to the Interrupt Enable Register (GMAC\_IER), or set individually by writing to the Interrupt Disable Register (GMAC\_IDR).

For test purposes there is a write-only function to this register that allows the bits in the Interrupt Status Register to be set or cleared, regardless of the state of the mask register. A write to this register directly affects the state of the corresponding bit in the Interrupt Status Register, causing an interrupt to be generated if a 1 is written.

The following values are valid for all listed bit names of this register when read:

0: The corresponding interrupt is enabled.

1: The corresponding interrupt is not enabled.

|        |        |        |           |       |          |       |        |        |

### 37.8.14 GMAC PHY Maintenance Register

**Name:** GMAC\_MAN  
**Offset:** 0x034  
**Reset:** 0x00000000  
**Property:** Read/Write

This register is a shift register. Writing to it starts a shift operation which is signaled completed when bit 2 is set in the Network Status Register (GMAC\_NSR). It takes about 2000 MCK cycles to complete, when MDC is set for MCK divide by 32 in the Network Configuration Register. An interrupt is generated upon completion.

During this time, the MSB of the register is output on the MDIO pin and the LSB updated from the MDIO pin with each MDC cycle. This causes transmission of a PHY management frame on MDIO. Refer also to section 22.2.4.5 of the IEEE 802.3 standard.

Reading during the shift operation returns the current contents of the shift register. At the end of management operation, the bits will have shifted back to their original locations. For a read operation, the data bits are updated with data read from the PHY. It is important to write the correct values to the register to ensure a valid PHY management frame is produced.

The MDIO interface can read IEEE 802.3 clause 45 PHYs, as well as clause 22 PHYs. To read clause 45 PHYs, bit 30 should be written with a '0' rather than a '1'. To write clause 45 PHYs, bits 31:28 should be written as 0x1:

| PHY       | Access         | Bit Value |       |       |       |
|-----------|----------------|-----------|-------|-------|-------|
|           |                | WZO       | CLTTO | OP[1] | OP[0] |
| Clause 22 | Read           | 0         | 1     | 1     | 0     |
|           | Write          | 0         | 1     | 0     | 1     |
| Clause 45 | Read           | 0         | 0     | 1     | 1     |
|           | Write          | 0         | 0     | 0     | 1     |
|           | Read + Address | 0         | 0     | 1     | 0     |

For a description of MDC generation, see also the 'GMAC Network Configuration Register' (GMAC\_NCR) description.

| Value | Description |
|-------|-------------|
| 01    | Write       |
| 10    | Read        |
| Other | Reserved    |

**Bits 27:23 – PHYA[4:0]** PHY Address

**Bits 22:18 – REGA[4:0]** Register Address

Specifies the register in the PHY to access.

**Bits 17:16 – WTN[1:0]** Write Ten

Must be written to '10'.

| Value | Description |
|-------|-------------|
| 10    | Mandatory   |
| Other | Reserved    |

**Bits 15:0 – DATA[15:0]** PHY Data

For a write operation, this field is written with the data to be written to the PHY.

After a read operation, this field contains the data read from the PHY.

**37.8.15 GMAC Receive Pause Quantum Register**

**Name:** GMAC\_RPQ  
**Offset:** 0x038  
**Reset:** 0x00000000  
**Property:** -

**Bits 15:0 – RPQ[15:0]** Received Pause Quantum  
 Stores the current value of the Receive Pause Quantum Register which is decremented every 512 bit times.

**37.8.16 GMAC Transmit Pause Quantum Register**

**Name:** GMAC\_TPQ  
**Offset:** 0x03C  
**Reset:** 0x0000FFFF  
**Property:** -

**Bits 15:0 – TPQ[15:0]** Transmit Pause Quantum  
 Written with the pause quantum value for pause frame transmission.

**37.8.17 GMAC TX Partial Store and Forward Register**

**Name:** GMAC\_TPSF  
**Offset:** 0x040  
**Reset:** 0x00000FFF  
**Property:** -

**Bit 31 – ENTXP** Enable TX Partial Store and Forward Operation

**Bits 11:0 – TPB1ADR[11:0]** Transmit Partial Store and Forward Address  
 Watermark value.

**37.8.18 GMAC RX Partial Store and Forward Register**

**Name:** GMAC\_RPSF  
**Offset:** 0x044  
**Reset:** 0x00000FFF  
**Property:** -

**Bits 15:0 – ADDR[15:0] Specific Address n**

The most significant bits of the destination address, that is, bits 47:32.

**37.8.24 GMAC Type ID Match n Register**

**Name:** GMAC\_TIDMx  
**Offset:** 0xA8 + (x-1)\*0x04 [x=1..4]  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 31 – ENIDn Enable Copying of TID Matched Frames**

| Value | Description                                  |
|-------|--|
| 0     | TID n is not part of the comparison match.   |
| 1     | TID n is processed for the comparison match. |

**Bits 15:0 – TID[15:0] Type ID Match n**

For use in comparisons with received frames type ID/length frames.

### 37.8.25 GMAC Wake on LAN Register

**Name:** GMAC\_WOL  
**Offset:** 0x0B8  
**Reset:** 0x00000000  
**Property:** -

| Access |     | R/W                     | R/W | R/W | R/W | R/W | R/W | R/W | R/W |  |
| Reset  |     | 0                       | 0   | 0   | 0   | 0   | 0   | 0   | 0   |  |

#### Bit 19 – MTI Multicast Hash Event Enable

| Value | Description                               |
|-------|---|
| 0     | Wake on LAN multicast hash Event disabled |
| 1     | Wake on LAN multicast hash Event enabled  |

#### Bit 18 – SA1 Specific Address Register 1 Event Enable

| Value | Description  |
|-------|--|
| 0     | Wake on Specific Address Register 1 Event disabled |
| 1     | Wake on Specific Address Register 1 Event enabled  |

#### Bit 17 – ARP ARP Request Event Enable

| Value | Description                            |
|-------|--|
| 0     | Wake on LAN ARP request Event disabled |
| 1     | Wake on LAN ARP request Event enabled  |

#### Bit 16 – MAG Magic Packet Event Enable

| Value | Description                             |
|-------|---|
| 0     | Wake on LAN magic packet Event disabled |
| 1     | Wake on LAN magic packet Event enabled  |

#### Bits 15:0 – IP[15:0] ARP Request IP Address

Wake on LAN ARP request IP address. Written to define the 16 least significant bits of the target IP address that is matched to generate a Wake on LAN event.

| Value         | Description  |
|---------------|--|
| 0x0000        | No Event generated, even if matched by the received frame.             |
| 0x0001-0xFFFF | Wake on LAN Event generated for matching LSB of the target IP address. |

**37.8.26 GMAC IPG Stretch Register**

**Name:** GMAC\_IPGS  
**Offset:** 0x0BC  
**Reset:** 0x00000000  
**Property:** -

**Bits 15:0 – FL[15:0] Frame Length**

Bits FL[7:0] are multiplied with the previously transmitted frame length (including preamble), and divided by

$$FL[15:8]+1 \text{ (adding 1 to prevent division by zero). } RESULT = \frac{FL[7:0]}{F[15+8]+1}$$

If RESULT > 96 and the IP Stretch Enable bit in the Network Configuration Register (GMAC\_NCFGR.IPGSEN) is written to '1', RESULT is used for the transmit inter-packet-gap.

**37.8.27 GMAC Stacked VLAN Register**

**Name:** GMAC\_SVLAN  
**Offset:** 0x0C0  
**Reset:** 0x00000000  
**Property:** -

|        |     |                 |     |     |     |     |     |     |     |
|--------|-----|-----------------|-----|-----|-----|-----|-----|-----|-----|

**Bit 31 – ESVLAN** Enable Stacked VLAN Processing Mode  
 0: Disable the stacked VLAN processing mode  
 1: Enable the stacked VLAN processing mode

| Value | Description                      |
|-------|----------------------------------|
| 0     | Stacked VLAN Processing disabled |
| 1     | Stacked VLAN Processing enabled  |

**Bits 15:0 – VLAN\_TYPE[15:0]** User Defined VLAN\_TYPE Field  
 When Stacked VLAN is enabled (ESVLAN=1), the first VLAN tag in a received frame will only be accepted if the VLAN type field is equal to this user defined VLAN\_TYPE, OR equal to the standard VLAN type (0x8100).  
**Note:** The second VLAN tag of a Stacked VLAN packet will only be matched correctly if its VLAN\_TYPE field equals 0x8100.

**37.8.28 GMAC Transmit PFC Pause Register**

**Name:** GMAC\_TPFCP  
**Offset:** 0x0C4  
**Reset:** 0x00000000  
**Property:** -

**Bits 15:8 – PQ[7:0] Pause Quantum**

When the Remove FCS bit in the GMAC Network Configuration register (GMAC\_NCFGR.RFCS) is written to '1', and one or more bits in this bit field are written to '0', the associated PFC pause frame's pause quantum field value is taken from the Transmit Pause Quantum register (GMAC\_TPQ).

For each entry equal to '1' in this bit field, the pause quantum associated with that entry will be zero.

**Bits 7:0 – PEV[7:0] Priority Enable Vector**

When the Remove FCS bit in the GMAC Network Configuration register (GMAC\_NCFGR.RFCS) is written to '1', the priority enable vector of the PFC priority-based pause frame is set to the value stored in this bit field.

**Bits 15:0 – PFTX[15:0] Pause Frames Transmitted Register**

This register counts the number of pause frames transmitted. Only pause frames triggered by the register interface or through the external pause pins are counted as pause frames. Pause frames received through the FIFO interface are counted in the frames transmitted counter.

**Bits 17:0 – MCOL[17:0] Multiple Collision**

This register counts the number of frames experiencing between two and fifteen collisions prior to being successfully transmitted, i.e., no underrun and not too many retries.

**37.8.54 GMAC Excessive Collisions Register**

**Name:** GMAC\_EC  
**Offset:** 0x140  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – XCOL[9:0] Excessive Collisions**

This register counts the number of frames that failed to be transmitted because they experienced 16 collisions.

**37.8.55 GMAC Late Collisions Register**

**Name:** GMAC\_LC  
**Offset:** 0x144  
**Reset:** 0x00000000  
**Property:** -

**Bits 9:0 – LCOL[9:0] Late Collisions**

This register counts the number of late collisions occurring after the slot time (512 bits) has expired. In 10/100 mode, late collisions are counted twice i.e., both as a collision and a late collision. In gigabit mode, a late collision causes the transmission to be aborted, thus the single and multi collision registers are not updated.

**37.8.56 GMAC Deferred Transmission Frames Register**

**Name:** GMAC\_DTF  
**Offset:** 0x148  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 17:0 – DEFT[17:0] Deferred Transmission**

This register counts the number of frames experiencing deferral due to carrier sense being active on their first attempt at transmission. Frames involved in any collision are not counted nor are frames that experienced a transmit underrun.

**37.8.57 GMAC Carrier Sense Errors Register**

**Name:** GMAC\_CSE  
**Offset:** 0x14C  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – CSR[9:0] Carrier Sense Error**

This register counts the number of frames transmitted with carrier sense was not seen during transmission or where carrier sense was deasserted after being asserted in a transmit frame without collision (no underrun). Only incremented in half duplex mode. The only effect of a carrier sense error is to increment this register. The behavior of the other statistics registers is unaffected by the detection of a carrier sense error.

**37.8.58 GMAC Octets Received Low Register**

**Name:** GMAC\_ORLO  
**Offset:** 0x150  
**Reset:** 0x00000000  
**Property:** -

When reading the Octets Transmitted and Octets Received Registers, bits [31:0] should be read prior to bits [47:32] to ensure reliable operation.

**Bits 31:0 – RXO[31:0] Received Octets**

Received octets in frame without errors [31:0]. The number of octets received in valid frames of any type. This counter is 48-bits and is read through two registers. This count does not include octets from pause frames, and is only incremented if the frame is successfully filtered and copied to memory.

**37.8.59 GMAC Octets Received High Register**

**Name:** GMAC\_ORHI  
**Offset:** 0x154  
**Reset:** 0x00000000  
**Property:** -

When reading the Octets Transmitted and Octets Received Registers, bits 31:0 should be read prior to bits 47:32 to ensure reliable operation.

**Bits 31:0 – NFRX[31:0] 1519 to Maximum Byte Frames Received without Error**

This bit field counts the number of 1519 Byte or above frames successfully received without error. Maximum frame size is determined by the Maximum Frame Size bit (MAXFS, 1536 Bytes) or Jumbo Frame Size bit (JFRAME, 10240 Bytes) in the Network Configuration Register (GMAC\_NCFGR). Excludes pause frames, and is only incremented if the frame is successfully filtered and copied to memory.

**37.8.71 GMAC Undersized Frames Received Register**

**Name:** GMAC\_UFR  
**Offset:** 0x184  
**Reset:** 0x00000000  
**Property:** -

**Bits 9:0 – UFRX[9:0] Undersize Frames Received**

This bit field counts the number of frames received less than 64 bytes in length (10/100 mode or gigabit mode, full duplex) that do not have either a CRC error or an alignment error.

In gigabit mode, half duplex, this bit field counts either frames not conforming to the minimum slot time of 512 bytes or frames not conforming to the minimum frame size once bursting is active.

**37.8.72 GMAC Oversized Frames Received Register**

**Name:** GMAC\_OFR  
**Offset:** 0x188  
**Reset:** 0x00000000  
**Property:** -

**Bits 9:0 – OFRX[9:0] Oversized Frames Received**

This pit field counts the number of frames received exceeding 1518 Bytes in length (1536 Bytes if GMAC\_NCFGR.MAXFS is written to '1', 10240 Bytes if GMAC\_NCFGR.JFRAME=1) but do not have either a CRC error, an alignment error, nor a receive symbol error.

**37.8.73 GMAC Jabbers Received Register**

**Name:** GMAC\_JR  
**Offset:** 0x18C  
**Reset:** 0x00000000  
**Property:** -

**Bits 9:0 – JR[X[9:0]** Jabbers Received

This bit field counts the number of frames received exceeding 1518 Bytes in length (1536 Bytes if GMAC\_NCFGR.MAXFS is written to '1', 10240 Bytes if GMAC\_NCFGR.JFRAME=1) and have either a CRC error, an alignment error or a receive symbol error.

**37.8.74 GMAC Frame Check Sequence Errors Register**

**Name:** GMAC\_FCSE  
**Offset:** 0x190  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – FCKR[9:0] Frame Check Sequence Errors**

The register counts frames that are an integral number of bytes, have bad CRC and are between 64 and 1518 bytes in length (1536 Bytes if GMAC\_NCFGR.MAXFS is written to '1', 10240 Bytes if GMAC\_NCFGR.JFRAME=1). This register is also incremented if a symbol error is detected and the frame is of valid length and has an integral number of bytes.

This register is incremented for a frame with bad FCS, regardless of whether it is copied to memory due to ignore FCS mode (enabled by writing GMAC\_NCFGR.IRXFCS=1).

**37.8.75 GMAC Length Field Frame Errors Register**

**Name:** GMAC\_LFFE  
**Offset:** 0x194  
**Reset:** 0x00000000  
**Property:** -

**Bits 9:0 – LFER[9:0] Length Field Frame Errors**

This bit field counts the number of frames received that have a measured length shorter than that extracted from the length field (Bytes 13 and 14). This condition is only counted if the value of the length field is less than 0x0600, the frame is not of excessive length and checking is enabled by writing a '1' to the Length Field Error Frame Discard bit in the Network Configuration Register (GMAC\_NCFGR.LFERD).

**37.8.76 GMAC Receive Symbol Errors Register**

**Name:** GMAC\_RSE  
**Offset:** 0x198  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – RXSE[9:0] Receive Symbol Errors**

This bit field counts the number of frames that had GRXER asserted during reception. For 10/100 mode symbol errors are counted regardless of frame length checks. For gigabit mode the frame must satisfy slot time requirements in order to count a symbol error. Additionally, in gigabit half duplex mode, carrier extension errors are also recorded. Receive symbol errors will also be counted as an FCS or alignment error if the frame is between 64 and 1518 Bytes (1536 Bytes if GMAC\_NCFGR.MAXFS=1, 10240 Bytes if GMAC\_NCFGR.JFRAME=1). If the frame is larger it will be recorded as a jabber error.

**37.8.77 GMAC Alignment Errors Register**

**Name:** GMAC\_AE  
**Offset:** 0x19C  
**Reset:** 0x00000000  
**Property:** Read-only

**Bits 9:0 – AER[9:0] Alignment Errors**

This bit field counts the frames that are not an integral number of bytes long and have bad CRC when their length is truncated to an integral number of Bytes and are between 64 and 1518 Bytes in length (1536 if GMAC\_NCFGR.MAXFS=1, 10240 Bytes if GMAC\_NCFGR.JFRAME=1). This register is also incremented if a symbol error is detected and the frame is of valid length and does not have an integral number of bytes.

**37.8.78 GMAC Receive Resource Errors Register**

**Name:** GMAC\_RRE  
**Offset:** 0x1A0  
**Reset:** 0x00000000  
**Property:** -

**Bits 9:0 – RXOVR[9:0] Receive Overruns**

This bit field counts the number of frames that are address recognized but were not copied to memory due to a receive overrun.

**37.8.80 GMAC IP Header Checksum Errors Register**

**Name:** GMAC\_IHCE  
**Offset:** 0x1A8  
**Reset:** 0x00000000  
**Property:** -

**Bits 7:0 – HCKER[7:0] IP Header Checksum Errors**

This register counts the number of frames discarded due to an incorrect IP header checksum, but are between 64 and 1518 Bytes (1536 Bytes if GMAC\_NCFGR.MAXFS=1 or 10240 Bytes if GMAC\_NCFGR.JFRAME=1) and do not have a CRC error, an alignment error, nor a symbol error.

**37.8.81 GMAC TCP Checksum Errors Register**

**Name:** GMAC\_TCE  
**Offset:** 0x1AC  
**Reset:** 0x00000000  
**Property:** -

**Bits 7:0 – TCKER[7:0] TCP Checksum Errors**

This register counts the number of frames discarded due to an incorrect TCP checksum, but are between 64 and 1518 Bytes (1536 Bytes if GMAC\_NCFGR.MAXFS=1 or 10240 Bytes if GMAC\_NCFGR.JFRAME=1) and do not have a CRC error, an alignment error, nor a symbol error.

**37.8.82 GMAC UDP Checksum Errors Register**

**Name:** GMAC\_UCE  
**Offset:** 0x1B0  
**Reset:** 0x00000000  
**Property:** -

**Bits 7:0 – UCKER[7:0] UDP Checksum Errors**

This register counts the number of frames discarded due to an incorrect UDP checksum, but are between 64 and 1518 Bytes (1536 Bytes if GMAC\_NCFGR.MAXFS=1 or 10240 Bytes if GMAC\_NCFGR.JFRAME=1) and do not have a CRC error, an alignment error, nor a symbol error.

**37.8.83 GMAC 1588 Timer Increment Sub-nanoseconds Register**

**Name:** GMAC\_TISUBN  
**Offset:** 0x1BC  
**Reset:** 0x00000000  
**Property:** -

**Bits 15:0 – LSBTIR[15:0]** Lower Significant Bits of Timer Increment Register  
 Lower significant bits of Timer Increment Register [15:0], giving a 24-bit timer\_increment counter. These bits are the sub-ns value which the 1588 timer will be incremented each clock cycle. Bit n = 2<sup>(n-16)</sup> ns giving a resolution of approximately 15.2E<sup>-15</sup> sec.

**37.8.84 GMAC 1588 Timer Seconds High Register**

**Name:** GMAC\_TSH  
**Offset:** 0x1C0  
**Reset:** 0x00000000  
**Property:** -

**Bits 29:0 – TNS[29:0] Timer Count in Nanoseconds**

This register is writable. It can also be adjusted by writes to the IEEE 1588 Timer Adjust Register. It increments by the value of the IEEE 1588 Timer Increment Register each clock cycle.

**37.8.87 GMAC 1588 Timer Adjust Register**

**Name:** GMAC\_TA  
**Offset:** 0x1D8  
**Reset:** 0x00000000  
**Property:** -

**Bit 7 – TCOMP** Transmit Complete

**Bit 6 – TFC** Transmit Frame Corruption Due to AHB Error

Transmit frame corruption due to AHB error—set if an error occurs whilst midway through reading transmit frame from the AHB, including HRESP errors and buffers exhausted mid frame.

**Bit 5 – RLEX** Retry Limit Exceeded or Late Collision

**Bit 2 – RXUBR** RX Used Bit Read

**Bit 1 – RCOMP** Receive Complete

**37.8.102 GMAC Transmit Buffer Queue Base Address Register Priority Queue x**

**Name:** GMAC\_TBQBAPQx  
**Offset:** 0x0440 + (x-1)\*0x04 [x=1..2]  
**Reset:** 0x00000000  
**Property:** Read/Write

These registers hold the start address of the transmit buffer queues (transmit buffers descriptor lists) for the additional queues and must be initialized to the address of valid descriptors, even if the priority queues are not used.

**Bits 31:2 – RXBQBA[29:0]** Receive Buffer Queue Base Address  
 Holds the address of the start of the receive queue.

**37.8.104 GMAC Receive Buffer Size Register Priority Queue x**

**Name:** GMAC\_RBSRPQx  
**Offset:** 0x04A0 + (x-1)\*0x04 [x=1..2]  
**Reset:** 0x00000002  
**Property:** Read/Write

**Bits 15:0 – RBS[15:0] Receive Buffer Size**

DMA receive buffer size in AHB system memory. The value defined by these bits determines the size of buffer to use in main AHB system memory when writing received data.

The value is defined in multiples of 64 Bytes such that a value of 0x01 corresponds to buffers of 64 Bytes, 0x02 corresponds to 128 Bytes etc.

Examples:

- 0x18: 1536 Bytes (1 × max length frame/buffer)
- 0xA0: 10240 Bytes (1 × 10K jumbo frame/buffer)

**Note:** This value should never be written as zero.

**37.8.105 GMAC Credit-Based Shaping Control Register**

**Name:** GMAC\_CBSCR  
**Offset:** 0x4BC  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bit 1 – QAE Queue A CBS Enable**

| Value | Description  |
|-------|--|
| 0     | Credit-based shaping on the second highest priority queue (queue A) is disabled. |
| 1     | Credit-based shaping on the second highest priority queue (queue A) is enabled.  |

**Bit 0 – QBE Queue B CBS Enable**

| Value | Description   |
|-------|---|
| 0     | Credit-based shaping on the highest priority queue (queue B) is disabled. |
| 1     | Credit-based shaping on the highest priority queue (queue B) is enabled.  |

**37.8.106 GMAC Credit-Based Shaping IdleSlope Register for Queue A**

**Name:** GMAC\_CBSISQA  
**Offset:** 0x4C0  
**Reset:** 0x00000000  
**Property:** Read/Write

Credit-based shaping must be disabled in the GMAC\_CBSCR before updating this register.

**Bits 31:0 – IS[31:0] IdleSlope**

IdleSlope value for queue A in Bytes per second.

The IdleSlope value is defined as the rate of change of credit when a packet is waiting to be sent. This must not exceed the port transmit rate which is dependent on the speed of operation, e.g., 100 Mb/second = 32'h017D7840. If 50% of bandwidth was to be allocated to a particular queue in 100 Mb/second mode, then the IdleSlope value for that queue would be calculated as 32'h017D7840 / 2.

**37.8.107 GMAC Credit-Based Shaping IdleSlope Register for Queue B**

**Name:** GMAC\_CBSISQB  
**Offset:** 0x4C4  
**Reset:** 0x00000000  
**Property:** Read/Write

Credit-based shaping must be disabled in the GMAC\_CBSCR before updating this register.

**Bits 31:0 – IS[31:0] IdleSlope**

IdleSlope value for queue B in bytes/second.

The IdleSlope value is defined as the rate of change of credit when a packet is waiting to be sent. This must not exceed the port transmit rate which is dependent on the speed of operation, e.g., 100 Mb/second = 32'h017D7840. If 50% of bandwidth was to be allocated to a particular queue in 100 Mb/sec mode, then the IdleSlope value for that queue would be calculated as 32'h017D7840 / 2

### 37.8.108 GMAC Screening Type 1 Register x Priority Queue

**Name:** GMAC\_ST1RPQx  
**Offset:** 0x0500 + x\*0x04 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

Screening type 1 registers are used to allocate up to priority queues to received frames based on certain IP or UDP fields of incoming frames.

|        |     |            |     |      |       |             |          |     |     |

**Bit 29 – UDPE** UDP Port Match Enable

When this bit is written to '1', the UDP Destination Port of the received UDP frame is matched against the value stored in the bit field UDPM.

**Bit 28 – DSTCE** Differentiated Services or Traffic Class Match Enable

When this bit is written to '1', the DS (differentiated services) field of the received IPv4 header or TC field (traffic class) of IPv6 headers are matched against the value stored in bit field DSTCM.

**Bits 27:12 – UDPM[15:0]** UDP Port Match

When UDP port match enable is set (UDPME=1), the UDP Destination Port of the received UDP frame is matched against this bit field.

**Bits 11:4 – DSTCM[7:0]** Differentiated Services or Traffic Class Match

When DS/TC match enable is set (DSTCE), the DS (differentiated services) field of the received IPv4 header or TC field (traffic class) of IPv6 headers are matched against this bit field.

**Bits 2:0 – QNB[2:0]** Queue Number

If a match is successful, then the queue value programmed in this bit field is allocated to the frame.

### 37.8.109 GMAC Screening Type 2 Register x Priority Queue

**Name:** GMAC\_ST2RPQx  
**Offset:** 0x0540 + x\*0x04 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

Screening type 2 registers are used to allocate up to 2 priority queues to received frames based on the VLAN priority field of received Ethernet frames.

**Bit 30 – COMPCE** Compare C Enable

| Value | Description   |
|-------|---|
| 0     | Compare C is disabled.  |
| 1     | Comparison via the register designated by index COMPC is enabled. |

**Bits 29:25 – COMPC[4:0]** Index of Screening Type 2 Compare Word 0/Word 1 register x

COMPC is a pointer to the compare registers GMAC\_ST2CW0x and GMAC\_ST2CW1x. When COMPCE=1, the compare is true if the data at the frame offset ANDed with the value MASKVAL is equal to the value of COMPVAL ANDed with the value of MASKVAL.

**Bit 24 – COMPBE** Compare B Enable

| Value | Description   |
|-------|---|
| 0     | Compare B is disabled.  |
| 1     | Comparison via the register designated by index COMPB is enabled. |

**Bits 23:19 – COMPB[4:0]** Index of Screening Type 2 Compare Word 0/Word 1 register x

COMPB is a pointer to the compare registers GMAC\_ST2CW0x and GMAC\_ST2CW1x. When COMPBE=1, the compare is true if the data at the frame offset ANDed with the value MASKVAL is equal to the value of COMPVAL ANDed with the value of MASKVAL.

**Bit 18 – COMP AE** Compare A Enable

| Value | Description  |
|-------|--|
| 0     | Compare A is disabled.   |
| 1     | Comparison via the register designated by index COMP A is enabled. |

**Bits 17:13 – COMPA[4:0]** Index of Screening Type 2 Compare Word 0/Word 1 register x  
COMPA is a pointer to the compare registers GMAC\_ST2CW0x and GMAC\_ST2CW1x. When COMPAE=1, the compare is true if the data at the frame offset ANDed with the value MASKVAL is equal to the value of COMPVAL ANDed with the value of MASKVAL.

**Bit 12 – ETHE** EtherType Enable

| Value | Description  |
|-------|--|
| 0     | EtherType match is disabled  |
| 1     | EtherType match with bits [15:0] of the register designated by the value in I2ETH is enabled |

**Bits 11:9 – I2ETH[2:0]** Index of Screening Type 2 EtherType register x  
When EtherType is enabled (ETHE=1), the EtherType field (last EtherType in the header if the frame is VLAN-tagged) is compared with bits [15:0] in the register designated by the value of this bit field.

**Bit 8 – VLANE** VLAN Enable

| Value | Description           |
|-------|-----------------------|
| 0     | VLAN match disabled   |
| 1     | VLAN match is enabled |

**Bits 6:4 – VLANP[2:0]** VLAN Priority

When VLAN match is enabled (VLANE=1), the VLAN Priority field of the received frame is matched against the value of this bit field.

**Bits 2:0 – QNB[2:0]** Queue Number

If a match is successful, then the queue value programmed in QNB is allocated to the frame.

**37.8.110 GMAC Interrupt Enable Register Priority Queue x**

**Name:** GMAC\_IERPQx  
**Offset:** 0x0600 + (x-1)\*0x04 [x=1..2]  
**Reset:** –  
**Property:** Write-only

The following values are valid for all listed bit names of this register:

0: No effect.

1: Enables the corresponding interrupt.

|        |       |     |      |    |       |       |       |    |

**37.8.111 GMAC Interrupt Disable Register Priority Queue x**

**Name:** GMAC\_IDRPQx  
**Offset:** 0x0620 + (x-1)\*0x04 [x=1..2]  
**Reset:** –  
**Property:** Write-only

The following values are valid for all listed bit names of this register:

0: No effect.

1: Disables the corresponding interrupt.

**Bit 11 – HRESP** HRESP Not OK

**Bit 10 – ROVR** Receive Overrun

**Bit 7 – TCOMP** Transmit Complete

**Bit 6 – TFC** Transmit Frame Corruption Due to AHB Error

**Bit 5 – RLEX** Retry Limit Exceeded or Late Collision

**Bit 2 – RXUBR** RX Used Bit Read

**Bit 1 – RCOMP** Receive Complete

### 37.8.112 GMAC Interrupt Mask Register Priority Queue x

**Name:** GMAC\_IMRPQx  
**Offset:** 0x0640 + (x-1)\*0x04 [x=1..2]  
**Reset:** 0x00000000  
**Property:** Read/Write

A read of this register returns the value of the receive complete interrupt mask.

A write to this register directly affects the state of the corresponding bit in the Interrupt Status Register, causing an interrupt to be generated if a '1' is written.

The following values are valid for all listed bit names of this register:

0: Corresponding interrupt is enabled.

1: Corresponding interrupt is disabled.

|        |       |     |      |    |       |       |       |    |

**Bit 11 – HRESP** HRESP Not OK

**Bit 10 – ROVR** Receive Overrun

**Bit 7 – TCOMP** Transmit Complete

**Bit 6 – AHB** AHB Error

**Bit 5 – RLEX** Retry Limit Exceeded or Late Collision

**Bit 2 – RXUBR** RX Used Bit Read

**Bit 1 – RCOMP** Receive Complete

**37.8.113 GMAC Screening Type 2 EtherType Register x**

**Name:** GMAC\_ST2ERx  
**Offset:** 0x06E0 + x\*0x04 [x=0..3]  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 15:0 – COMPVAL[15:0] EtherType Compare Value**

When the bit GMAC\_ST2RPQ.ETHE is written to '1', the EtherType (last EtherType in the header if the frame is VLAN tagged) is compared with bits [15:0] in the register designated by GMAC\_ST2RPQ.I2ETH.

**37.8.114 GMAC Screening Type 2 Compare Word 0 Register x**

**Name:** GMAC\_ST2CW0x  
**Offset:** 0x0700 + x\*0x08 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

| Access |     | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        |     |               |     |     |     |     |     |     |     |
|        | Bit | 7             | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|        |     | MASKVAL[7:0]  |     |     |     |     |     |     |     |
| Access |     | R/W           | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Reset  |     | 0             | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 31:16 – COMPVAL[15:0] Compare Value**

The byte stored in bits [23:16] is compared against the first byte of the 2 bytes extracted from the frame.  
The byte stored in bits [31:24] is compared against the second byte of the 2 bytes extracted from the frame.

**Bits 15:0 – MASKVAL[15:0] Mask Value**

The value of MASKVAL ANDed with the 2 bytes extracted from the frame is compared to the value of MASKVAL ANDed with the value of COMPVAL.

**37.8.115 GMAC Screening Type 2 Compare Word 1 Register x**

**Name:** GMAC\_ST2CW1x  
**Offset:** 0x0704 + x\*0x08 [x=0..1]  
**Reset:** 0x00000000  
**Property:** Read/Write

**Bits 8:7 – OFFSSTRT[1:0] Ethernet Frame Offset Start**

| Value | Name       | Description   |
|-------|------------|---|
| 0     | FRAMESTART | Offset from the start of the frame                  |
| 1     | ETHERTYPE  | Offset from the byte after the EtherType field      |
| 2     | IP         | Offset from the byte after the IP header field      |
| 3     | TCP_UDP    | Offset from the byte after the TCP/UDP header field |

**Bits 6:0 – OFFSVAL[6:0] Offset Value in Bytes**

The value of OFFSVAL ranges from 0 to 127 bytes, and is counted from either the start of the frame, the byte after the EtherType field (last EtherType in the header if the frame is VLAN tagged), the byte after the IP header (IPv4 or IPv6) or the byte after the TCP/UDP header.

## 38. USB High-Speed Interface (USBHS)

### 38.1 Description

The USB High-Speed Interface (USBHS) complies with the Universal Serial Bus (USB) 2.0 specification. <sup>(1)</sup>

Each pipe/endpoint can be configured in one of several USB transfer types. It can be associated with one, two or three banks of a DPRAM used to store the current data payload. If two or three banks are used, then one DPRAM bank is read or written by the CPU or the DMA, while the other is read or written by the USBHS core. This feature is mandatory for isochronous pipes/endpoints.

The following table describes the hardware configuration of the USB MCU device.

**Table 38-1. Description of USB Pipes/Endpoints**

| Pipe/Endpoint | Mnemonic | Max. Number Banks | DMA | High Band Width | Max. Pipe/Endpoint Size | Type                               |
|---------------|----------|-------------------|-----|-----------------|-------------------------|------------------------------------|
| 0             | PEP_0    | 1                 | N   | N               | 64                      | Control                            |
| 1             | PEP_1    | 3                 | Y   | Y               | 1024                    | Isochronous/Bulk/Interrupt/Control |
| 2             | PEP_2    | 3                 | Y   | Y               | 1024                    | Isochronous/Bulk/Interrupt/Control |

| 7             | PEP_7    | 2                 | Y   | Y               | 1024                    | Isochronous/Bulk/Interrupt/Control |
| 8             | PEP_8    | 2                 | N   | Y               | 1024                    | Isochronous/Bulk/Interrupt/Control |
| 9             | PEP_9    | 2                 | N   | Y               | 1024                    | Isochronous/Bulk/Interrupt/Control |

**Note:**

1. High-bandwidth isochronous transfers supported in device but not host mode.

### 38.2 Embedded Characteristics

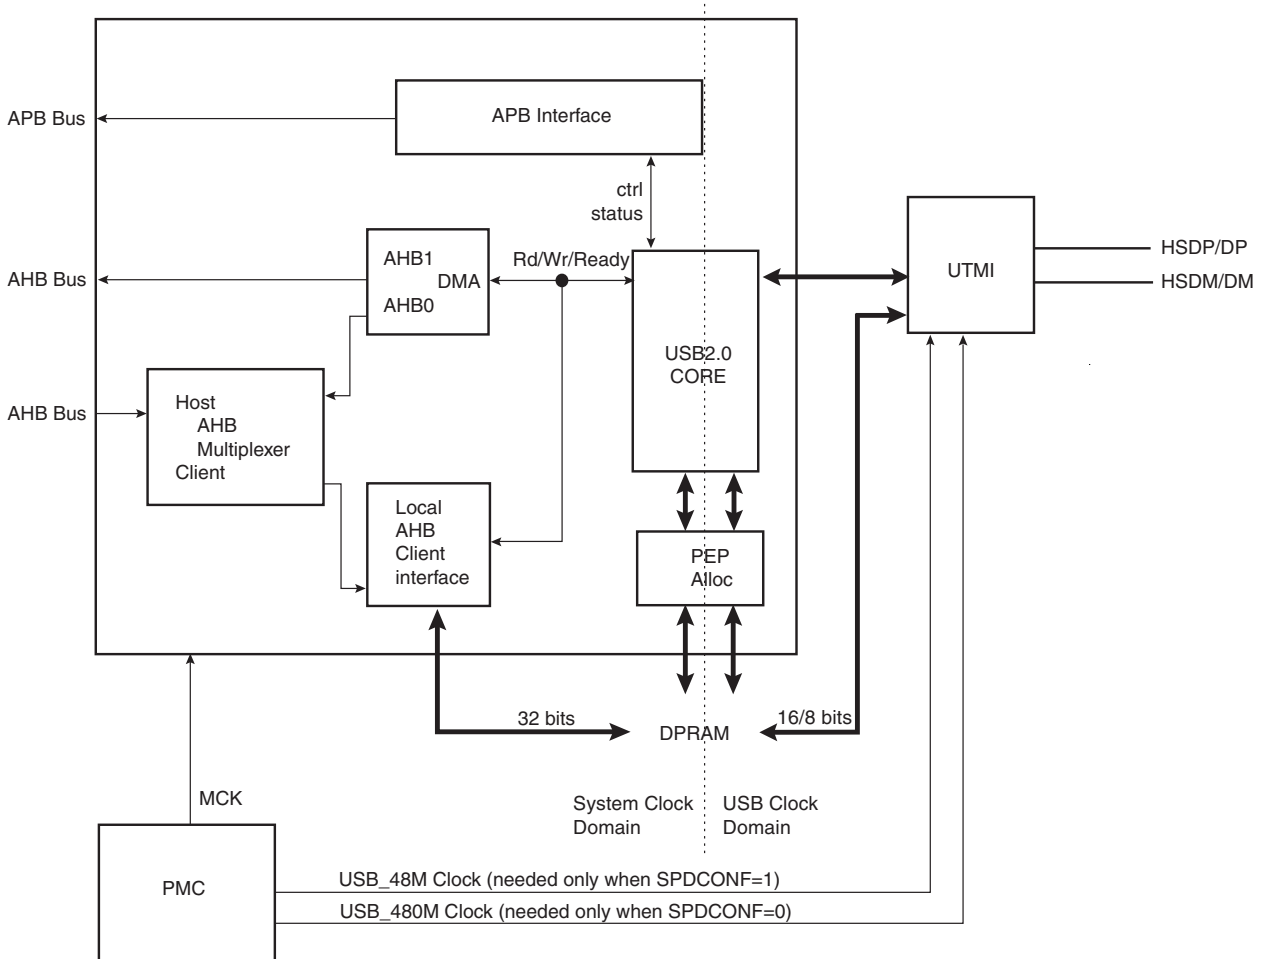

- Compatible with the USB 2.0 Specification
- Supports High-Speed (480 Mbps), Full-Speed (12 Mbps) and Low-Speed (1.5 Mbps) Communication
- 9 Pipes/Endpoints
- 4096 bytes of Embedded Dual-Port RAM (DPRAM) for Pipes/Endpoints
- Up to 3 Memory Banks per Pipe/Endpoint (not for Control Pipe/Endpoint)
- Flexible Pipe/Endpoint Configuration and Management with Dedicated DMA Channels
- On-chip UTMI Transceiver including Pull-ups/Pull-downs

### 38.3 Block Diagram

The USBHS provides a hardware device to interface a USB link to a data flow stored in a dual-port RAM (DPRAM).

In normal operation (SPDCONF = 0), the UTMI transceiver requires the UTMI PLL (480 MHz). In case of full-speed or low-speed only, for a lower consumption (SPDCONF = 1), the UTMI transceiver only requires 48 MHz.

**Figure 38-1. USBHS Block Diagram**

### 38.4 Signal Description

**Table 38-2. Signal Description**

| Name    | Description                    | Type         |
|---------|--------------------------------|--------------|
| HSDM/DM | HS/FS Differential Data Line - | Input/Output |
| HSDP/DP | HS/FS Differential Data Line + | Input/Output |

### 38.5 Product Dependencies

#### 38.5.1 I/O Lines

A regular PIO line must be used to control VBUS. This is configured in the I/O Controller.

### 38.5.2 Clocks

The clock for the USBHS bus interface is generated by the Power Management Controller. This clock can be enabled or disabled in the Power Management Controller. It is recommended to disable the USBHS before disabling the clock, to avoid freezing the USBHS in an undefined state.

Before enabling the USB clock in the Power Management Controller, the USBHS must be enabled (by writing a one to the USBHS\_CTRL.USBE bit and a zero to the USBHS\_CTRL.FRZCLK bit).

The USBHS can work in two modes:

- Normal mode (SPDCONF = 0) where High speed, Full speed and Low speed are available.
- Low-power mode (SPDCONF = 1) where Full speed and Low speed are available.

To ensure successful startup, follow the sequences below:

- In Normal mode:

1. Enable the USBHS peripheral clock. This is done via the register PMC\_PCER.
2. Enable the USBHS (UIMOD, USBE = 1, FRZCLK = 0).
3. Enable the UPLL 480 MHz.
4. Wait for the UPLL 480 MHz to be considered as locked by the PMC.

- In Low-power mode:

1. As USB\_48M must be set to 48 MHz (refer to the section “Power Management Controller (PMC)”), select either the PLLA or the UPLL (previously set to ON), and program the PMC\_USB register (source selection and divider).
2. Enable the USBHS peripheral clock (PMC\_PCER).
3. Put the USBHS in Low-power mode (SPDCONF = 1).
4. Enable the USBHS (UIMOD, USBE = 1, FRZCLK = 0).
5. Enable the USBCK bit (PMC\_SCER).

[31. Power Management Controller \(PMC\)](#)

### 38.5.3 Interrupt Sources

The USBHS interrupt request line is connected to the interrupt controller. Using the USBHS interrupt requires the interrupt controller to be programmed first.

### 38.5.4 USB Pipe/Endpoint x FIFO Data Register (USBFIFOxDATA)

The application has access to each pipe/endpoint FIFO through its reserved 32 KB address space. The application can access a 64-KB buffer linearly or fixedly as the DPRAM address increment is fully handled by hardware. Byte, half-word and word accesses are supported. Data should be accessed in a big-endian way.

Disabling the USBHS (by writing a zero to the USBHS\_CTRL.USBE bit) does not reset the DPRAM.

## 38.6 Functional Description

### 38.6.1 USB General Operation

#### 38.6.1.1 Power-On and Reset

The following figure describes the USBHS general states.

**Figure 38-2. General States**

After a hardware reset, the USBHS is in Reset state. In this state:

- The USBHS is disabled. The USBHS Enable bit in the General Control register (USBHS\_CTRL.USBE) is zero.
- The USBHS clock is stopped in order to minimize power consumption. The Freeze USB Clock bit (USBHS\_CTRL.FRZCLK) is set.
- The UTMI is in Suspend mode.
- The internal states and registers of the Device and Host modes are reset.
- The DPRAM is not cleared and is accessible.

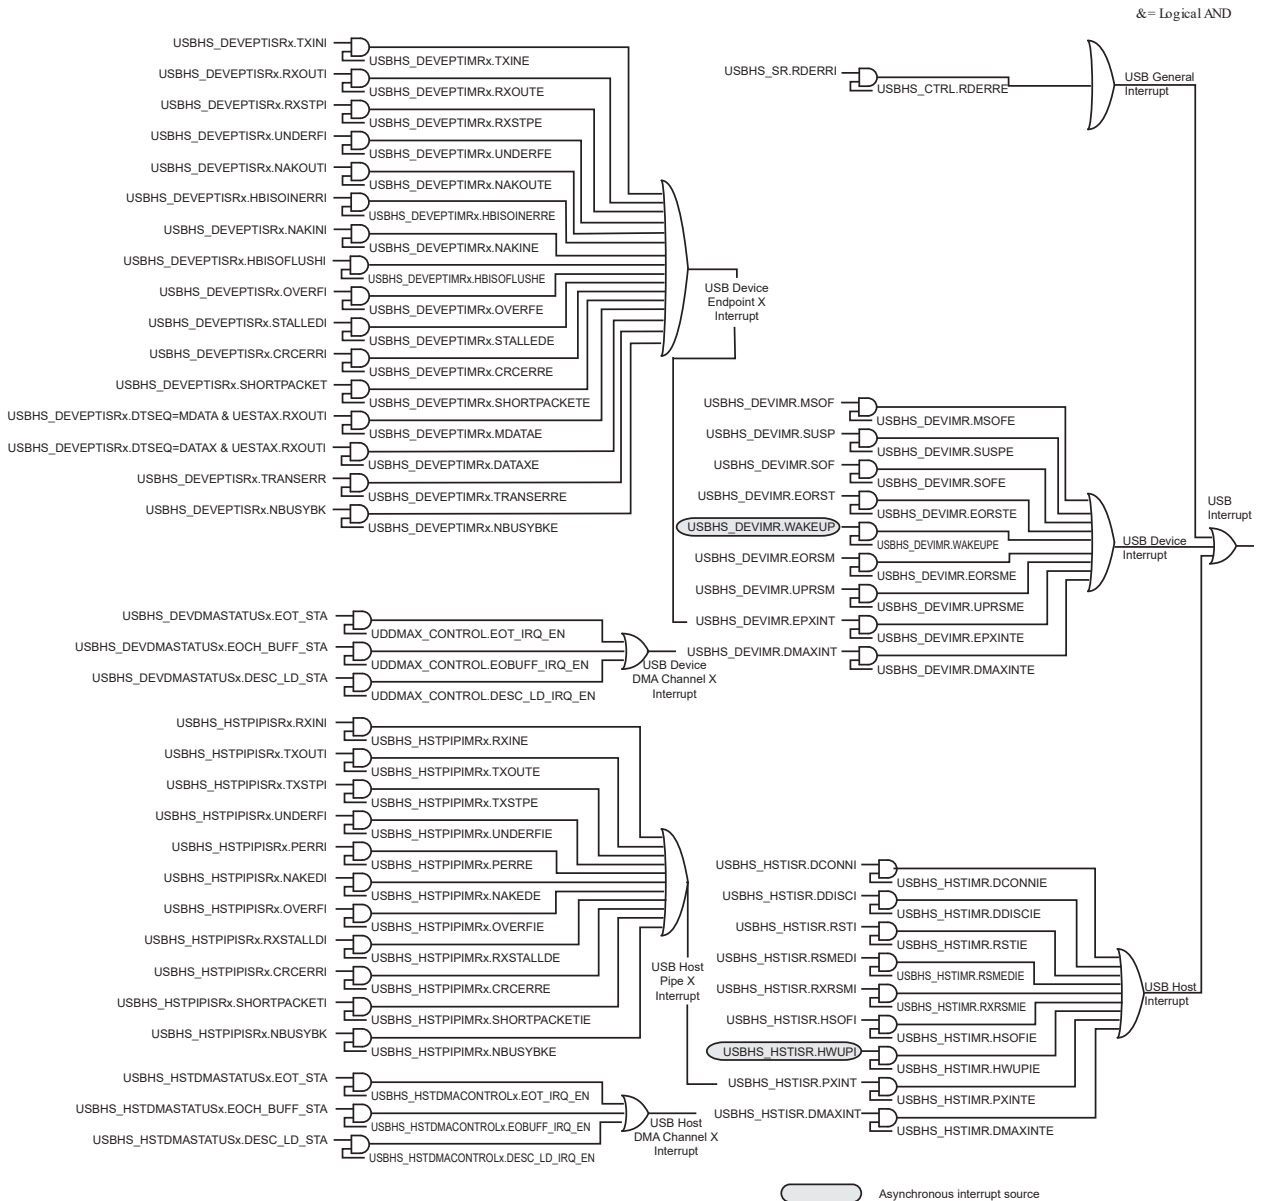

After writing a one to USBHS\_CTRL.USBE, the USBHS enters the Device or the Host mode in idle state.

The USBHS can be disabled at any time by writing a zero to USBHS\_CTRL.USBE. This acts as a hardware reset, except that the USBHS\_CTRL.FRZCLK, USBHS\_CTRL.UIMOD and USBHS\_DEVCTRL.LS bits are not reset.

### 38.6.1.2 Interrupts

One interrupt vector is assigned to the USB interface. The following figure shows the structure of the USB interrupt system.

**Figure 38-3. Interrupt System**

See [Interrupts](#) in the Device Operation section and [Interrupts](#) in the Host Operation section for further details about device and host interrupts.

There are two kinds of general interrupts: processing, i.e., their generation is part of the normal processing, and exception, i.e., errors (not related to CPU exceptions).

### 38.6.1.3 MCU Power Modes

#### USB Suspend Mode

In Peripheral mode, the Suspend Interrupt bit in the Device Global Interrupt Status register (USBHS\_DEVISR.SUSP) indicates that the USB line is in Suspend mode. In this case, the transceiver is automatically set in Suspend mode to reduce consumption.

#### Clock Frozen

The USBHS can be frozen when the USB line is in the Suspend mode, by writing a one to the USBHS\_CTRL.FRZCLK bit, which reduces power consumption.

In this case, it is still possible to access the following:

- USBHS\_CTRL.FRZCLK, USBHS\_CTRL.USBE and USBHS\_DEVCTRL.LS bits

Moreover, when USBHS\_CTRL.FRZCLK = 1, only the asynchronous interrupt sources can trigger the USB interrupt:

- Wakeup Interrupt (USBHS\_DEVISR.WAKEUP)
- Host Wakeup Interrupt (USBHS\_HSTISR.HWUPI)

### 38.6.1.4 Speed Control

#### Device Mode

When the USB interface is in Device mode, the speed selection (Full-speed or High-speed) is performed automatically by the USBHS during the USB reset according to the host speed capability. At the end of the USB reset, the USBHS enables or disables high-speed terminations and pull-up.

It is possible to set the USBHS\_DEVCTRL.SPDCONF.

#### Host Mode

When the USB interface is in Host mode, internal pull-down resistors are connected on both D+ and D- and the interface detects the speed of the connected device, which is reflected by the Speed Status (USBHS\_SR.SPEED) field.

### 38.6.1.5 DPRAM Management

Pipes and endpoints can only be allocated in ascending order, from pipe/endpoint 0 to the last pipe/endpoint to be allocated. The user should therefore configure them in the same order.

The allocation of a pipe/endpoint  $x$  starts when the Endpoint Memory Allocate bit in the Endpoint  $x$  Configuration register (USBHS\_DEVEPTCFGx.ALLOC) is written to one. Then, the hardware allocates a memory area in the DPRAM and inserts it between the  $x - 1$  and  $x + 1$  pipes/endpoints. The  $x + 1$  pipe/endpoint memory window slides up and its data is lost. Note that the following pipe/endpoint memory windows (from  $x + 2$ ) do not slide.

Disabling a pipe, by writing a zero to the Pipe  $x$  Enable bit in the Host Pipe register (USBHS\_HSTPIP.PENx), or disabling an endpoint, by writing a zero to the Endpoint  $x$  Enable bit in the Device Endpoint register (USBHS\_DEVEPT.EPENx), does not reset the USBHS\_DEVEPTCFGx.ALLOC bit or the Pipe/Endpoint configuration:

- Pipe Configuration
  - Pipe Banks (USBHS\_HSTPIPCFGx.PBK)
  - Pipe Size (USBHS\_HSTPIPCFGx.PSIZE)
  - Pipe Token (USBHS\_HSTPIPCFGx.PTOKEN)
  - Pipe Type (USBHS\_HSTPIPCFGx.PTYPE)
  - Pipe Endpoint Number (USBHS\_HSTPIPCFGx.PEPNUM)
  - Pipe Interrupt Request Frequency (USBHS\_HSTPIPCFGx.INTFRQ)
- Endpoint Configuration
  - Endpoint Banks (USBHS\_DEVEPTCFGx.EPBK)
  - Endpoint Size (USBHS\_DEVEPTCFGx.EPSIZE)
  - Endpoint Direction (USBHS\_DEVEPTCFGx.EPDIR)
  - Endpoint Type (USBHS\_DEVEPTCFGx.EPTYPE)

To free endpoint memory, the user must write a zero to the USBHS\_DEVEPTCFGx.ALLOC bit. The  $x + 1$  pipe/endpoint memory window then slides down and its data is lost. Note that the following pipe/endpoint memory windows (from  $x + 2$ ) do not slide.

The following figure illustrates the allocation and reorganization of the DPRAM in a typical example.

**Figure 38-4. Allocation and Reorganization of the DPRAM**

1. Pipes/endpoints 0 to 5 are enabled, configured and allocated in ascending order. Each pipe/endpoint then owns a memory area in the DPRAM.
2. Pipe/endpoint 3 is disabled, but its memory is kept allocated by the controller.
3. In order to free its memory, its USBHS\_DEVEPTCFGx.ALLOC bit is written to zero. The pipe/endpoint 4 memory window slides down, but pipe/endpoint 5 does not move.
4. If the user chooses to reconfigure pipe/endpoint 3 with a larger size, the controller allocates a memory area after the pipe/endpoint 2 memory area and automatically slides up the pipe/endpoint 4 memory window. Pipe/endpoint 5 does not move and a memory conflict appears as the memory windows of pipes/endpoints 4 and 5 overlap. The data of these pipes/endpoints is potentially lost.

**Note:** 1. The data of pipe or endpoint 0 cannot be lost (except if it is de-allocated) as the memory allocation and de-allocation may affect only higher pipes/endpoints.

**Note:** 2. Deactivating then reactivating the same pipe/endpoint with the same configuration only modifies temporarily the controller DPRAM pointer and size for this pipe/endpoint. Nothing changes in the DPRAM. Higher endpoints seem not to have been moved and their data is preserved as long as nothing has been written or received into them while changing the allocation state of the first pipe/endpoint.

**Note:** 3. When the user writes a one to the USBHS\_DEVEPTCFGx.ALLOC bit, the Configuration OK Status bit (USBHS\_DEVEPTISRx.CFGOK) is set only if the configured size and number of banks are correct as compared to the endpoint maximum allowed values and to the maximum FIFO size (i.e., the DPRAM size). The USBHS\_DEVEPTISRx.CFGOK value does not consider memory allocation conflicts.

### 38.6.1.6 Pad Suspend

Figure 38-5 shows the pad behavior.

**Figure 38-5. Pad Behavior**

- In Idle state, the pad is put in Low-power mode, i.e., the differential receiver of the USB pad is off, and internal pull-downs with a strong value (15 K) are set in HSDP/D and HSDM/DM to avoid floating lines.
- In Active state, the pad is working.

Figure 38-6 illustrates the pad events leading to a PAD state change.

**Figure 38-6. Pad Events**

The USBHS\_DEVISR.SUSP bit is set and the Wakeup Interrupt (USBHS\_DEVISR.WAKEUP) bit is cleared when a USB “Suspend” state has been detected on the USB bus. This event automatically puts the USB pad in Idle state. The detection of a non-idle event sets USBHS\_DEVISR.WAKEUP, clears USBHS\_DEVISR.SUSP and wakes up the USB pad.

The pad goes to the Idle state if the USBHS is disabled or if the USBHS\_DEVCTRL.DETACH bit = 1. It returns to the Active state when USBHS\_CTRL.USBE = 1 and USBHS\_DEVCTRL.DETACH = 0.

## 38.6.2 USB Device Operation

### 38.6.2.1 Introduction

In Device mode, the USBHS supports high-, full- and low-speed data transfers.

In addition to the default control endpoint, 9 endpoints are provided, which can be configured with an isochronous, bulk or interrupt type, as described in [Table 38-1](#).

As the Device mode starts in Idle state, the pad consumption is reduced to the minimum.

### 38.6.2.2 Power-On and Reset

The following figure describes the USBHS Device mode main states.

**Figure 38-7. Device Mode Main States**

After a hardware reset, the USBHS Device mode is in Reset state. In this state:

- the USBHS clock is stopped to minimize power consumption (USBHS\_CTRL.FRZCLK = 1),
- the internal registers of the Device mode are reset,
- the endpoint banks are de-allocated,
- neither D+ nor D- is pulled up (USBHS\_DEVCTRL.DETACH = 1).

D+ or D- is pulled up according to the selected speed as soon as the USBHS\_DEVCTRL.DETACH bit is written to zero. See “Device Mode” for further details.

When the USBHS is enabled (USBHS\_CTRL.USBE = 1) in Device mode (USBHS\_CTRL.UIMOD = 1), its Device mode state enters Idle state with minimal power consumption. This does not require the USB clock to be activated.

The USBHS Device mode can be disabled and reset at any time by disabling the USBHS (by writing a zero to USBHS\_CTRL.USBE) or when the Host mode is enabled (USBHS\_CTRL.UIMOD = 0).

### 38.6.2.3 USB Reset

The USB bus reset is managed by hardware. It is initiated by a connected host.

When a USB reset is detected on the USB line, the following operations are performed by the controller:

- All endpoints are disabled, except the default control endpoint.
- The default control endpoint is reset (see 38.6.2.4. Endpoint Reset for more details).
- The data toggle sequence of the default control endpoint is cleared.
- At the end of the reset process, the End of Reset (USBHS\_DEVISR.EORST) bit is set.
- During a reset, the USBHS automatically switches to High-speed mode if the host is High-speed-capable (the reset is called High-speed reset). The user should observe the USBHS\_SR.SPEED field to know the speed running at the end of the reset (USBHS\_DEVISR.EORST = 1).

### 38.6.2.4 Endpoint Reset

An endpoint can be reset at any time by writing a one to the Endpoint x Reset bit USBHS\_DEVEPT.EPRSTx. This is recommended before using an endpoint upon hardware reset or when a USB bus reset has been received. This resets:

- the internal state machine of the endpoint,
- the receive and transmit bank FIFO counters,
- all registers of this endpoint (USBHS\_DEVEPTCFGx, USBHS\_DEVEPTISRx, the Endpoint x Control (USBHS\_DEVEPTIMRx) register), except its configuration (USBHS\_DEVEPTCFGx.ALLOC, USBHS\_DEVEPTCFGx.EPBK, USBHS\_DEVEPTCFGx.EPSIZE, USBHS\_DEVEPTCFGx.EPDIR, USBHS\_DEVEPTCFGx.EPTYPE) and the Data Toggle Sequence (USBHS\_DEVEPTISRx.DTSEQ) field.  
Note: The interrupt sources located in USBHS\_DEVEPTISRx are not cleared when a USB bus reset has been received.

The endpoint configuration remains active and the endpoint is still enabled.

The endpoint reset may be associated with a clear of the data toggle sequence as an answer to the CLEAR\_FEATURE USB request. This can be achieved by writing a one to the Reset Data Toggle Set bit (RSTDTS) in the Device Endpoint x Control Set register (this sets the Reset Data Toggle bit USBHS\_DEVEPTIMRx.RSTDTS).

In the end, the user has to write a zero to the USBHS\_DEVEPT.EPRSTx bit to complete the reset operation and to start using the FIFO.

### 38.6.2.5 Endpoint Activation

The endpoint is maintained inactive and reset (see "Endpoint Reset" for more information) as long as it is disabled (USBHS\_DEVEPT.EPENx = 0). USBHS\_DEVEPTISRx.DTSEQ is also reset.

The algorithm represented in the following figure must be followed to activate an endpoint.

**Figure 38-8. Endpoint Activation Algorithm**

As long as the endpoint is not correctly configured (USBHS\_HSTPIISRx.CFGOK = 0), the controller does not acknowledge the packets sent by the host to this endpoint.

The USBHS\_HSTPIISRx.CFGOK bit is set provided that the configured size and number of banks are correct as compared to the endpoint maximal allowed values (see the [Description of USB Pipes/Endpoints](#) table) and to the maximal FIFO size (i.e., the DPRAM size).

See "DPRAM Management" for additional information.

### 38.6.2.6 Address Setup

The USB device address is set up according to the USB protocol.

- After all kinds of resets, the USB device address is 0.
- The host starts a SETUP transaction with a SET\_ADDRESS (addr) request.
- The user writes this address to the USB Address (USBHS\_DEVCTRL.UADD) field, and writes a zero to the Address Enable (USBHS\_DEVCTRL.ADDEN) bit, so the actual address is still 0.
- The user sends a zero-length IN packet from the control endpoint.
- The user enables the recorded USB device address by writing a one to USBHS\_DEVCTRL.ADDEN.

Once the USB device address is configured, the controller filters the packets to accept only those targeting the address stored in USBHS\_DEVCTRL.UADD.

USBHS\_DEVCTRL.UADD and USBHS\_DEVCTRL.ADDEN must not be written all at once.

USBHS\_DEVCTRL.UADD and USBHS\_DEVCTRL.ADDEN are cleared:

- on a hardware reset,
- when the USBHS is disabled (USBHS\_CTRL.USBE = 0),
- when a USB reset is detected.

When USBHS\_DEVCTRL.UADD or USBHS\_DEVCTRL.ADDEN is cleared, the default device address 0 is used.

### 38.6.2.7 Suspend and Wakeup

When an idle USB bus state has been detected for 3 ms, the controller sets the Suspend (USBHS\_DEVISR.SUSP) interrupt bit. The user may then write a one to the USBHS\_CTRL.FRZCLK bit to reduce power consumption.

To recover from the Suspend mode, the user should wait for the Wakeup (USBHS\_DEVISR.WAKEUP) interrupt bit, which is set when a non-idle event is detected, then write a zero to USBHS\_CTRL.FRZCLK.

As the USBHS\_DEVISR.WAKEUP interrupt bit is set when a non-idle event is detected, it can occur whether the controller is in the Suspend mode or not. The USBHS\_DEVISR.SUSP and USBHS\_DEVISR.WAKEUP interrupts are thus independent, except that one bit is cleared when the other is set.

### 38.6.2.8 Detach

The reset value of the USBHS\_DEVCTRL.DETACH bit is one.

It is possible to initiate a device re-enumeration by simply writing a one, and then a zero, to USBHS\_DEVCTRL.DETACH.

USBHS\_DEVCTRL.DETACH acts on the pull-up connections of the D+ and D- pads. See “[Device Mode](#)” for further details.

### 38.6.2.9 Remote Wakeup

The Remote Wakeup request (also known as Upstream Resume) is the only one the device may send without a host invitation, assuming a host command allowing the device to send such a request was previously issued. The sequence is the following:

1. The USBHS must have detected a “Suspend” state on the bus, i.e., the Remote Wakeup request can only be sent after a USBHS\_DEVISR.SUSP interrupt has been set.
2. The user writes a one to the Remote Wakeup (USBHS\_DEVCTRL.RMWKUP) bit to send an upstream resume to the host for a remote wakeup. This will automatically be done by the controller after 5 ms of inactivity on the USB bus.
3. When the controller sends the upstream resume, the Upstream Resume (USBHS\_DEVISR.UPRSM) interrupt is set and USBHS\_DEVISR.SUSP is cleared.
4. USBHS\_DEVCTRL.RMWKUP is cleared at the end of the upstream resume.
5. When the controller detects a valid “End of Resume” signal from the host, the End of Resume (USBHS\_DEVISR.EORSM) interrupt is set.

### 38.6.2.10 STALL Request

For each endpoint, the STALL management is performed using:

- the STALL Request (USBHS\_DEVEPTIMRx.STALLRQ) bit to initiate a STALL request,
- the STALLed Interrupt (USBHS\_DEVEPTISRx.STALLEDI) bit, which is set when a STALL handshake has been sent.

To answer the next request with a STALL handshake, USBHS\_DEVEPTIMRx.STALLRQ has to be set by writing a one to the STALL Request Set (USBHS\_DEVEPTIERx.STALLRQS) bit. All following requests are discarded (USBHS\_DEVEPTISRx.RXOUTI, etc. is not be set) and handshaked with a STALL until the USBHS\_DEVEPTIMRx.STALLRQ bit is cleared, which is done when a new SETUP packet is received (for control endpoints) or when the STALL Request Clear (USBHS\_DEVEPTIMRx.STALLRQC) bit is written to one.

Each time a STALL handshake is sent, the USBHS\_DEVEPTISRx.STALLEDI bit is set by the USBHS and the PEP\_x interrupt is set.

#### Special Considerations for Control Endpoints

If a SETUP packet is received into a control endpoint for which a STALL is requested, the Received SETUP Interrupt (USBHS\_DEVEPTISRx.RXSTPI) bit is set and USBHS\_DEVEPTIMRx.STALLRQ and USBHS\_DEVEPTISRx.STALLEDI are cleared. The SETUP has to be ACKed.

This simplifies the enumeration process management. If a command is not supported or contains an error, the user requests a STALL and can return to the main task, waiting for the next SETUP request.

#### STALL Handshake and Retry Mechanism

The retry mechanism has priority over the STALL handshake. A STALL handshake is sent if the USBHS\_DEVEPTIMRx.STALLRQ bit is set and if no retry is required.

### 38.6.2.11 Management of Control Endpoints

#### Overview

A SETUP request is always ACKed. When a new SETUP packet is received, the USBHS\_DEVEPTISRx.RXSTPI is set; the Received OUT Data Interrupt (USBHS\_DEVEPTISRx.RXOUTI) bit is not.

The FIFO Control (USBHS\_DEVEPTIMRx.FIFOCON) bit and the Read/Write Allowed (USBHS\_DEVEPTISRx.RWALL) bit are irrelevant for control endpoints. The user never uses them on these endpoints. When read, their values are always zero.

Control endpoints are managed using:

- the USBHS\_DEVEPTISRx.RXSTPI bit, which is set when a new SETUP packet is received and which is cleared by firmware to acknowledge the packet and to free the bank;
- the USBHS\_DEVEPTISRx.RXOUTI bit, which is set when a new OUT packet is received and which is cleared by firmware to acknowledge the packet and to free the bank;
- the Transmitted IN Data Interrupt (USBHS\_DEVEPTISRx.TXINI) bit, which is set when the current bank is ready to accept a new IN packet and which is cleared by firmware to send the packet.

#### Control Write

Figure 38-9 shows a control write transaction. During the status stage, the controller does not necessarily send a NAK on the first IN token:

- if the user knows the exact number of descriptor bytes that must be read, it can then anticipate the status stage and send a zero-length packet after the next IN token, or
- it can read the bytes and wait for the NAKed IN Interrupt (USBHS\_DEVEPTISRx.NAKINI), which acknowledges that all the bytes have been sent by the host and that the transaction is now in the status stage.

**Figure 38-9. Control Write**

Figure 38-10 shows a control read transaction. The USBHS has to manage the simultaneous write requests from the CPU and the USB host.

**Figure 38-10. Control Read**

A NAK handshake is always generated on the first status stage command.

When the controller detects the status stage, all data written by the CPU is lost and clearing USBHS\_DEVEPTISRx.TXINI has no effect.

The user checks if the transmission or the reception is complete.

The OUT retry is always ACKed. This reception sets USBHS\_DEVEPTISRx.RXOUTI and USBHS\_DEVEPTISRx.TXINI. Handle this with the following software algorithm:

```

set TXINI
wait for RXOUTI OR TXINI
if RXOUTI, then clear bit and return
if TXINI, then continue
    
```

Once the OUT status stage has been received, the USBHS waits for a SETUP request. The SETUP request has priority over any other request and has to be ACKed. This means that any other bit should be cleared and the FIFO reset when a SETUP is received.

The user has to consider that the byte counter is reset when a zero-length OUT packet is received.

### 38.6.2.12 Management of IN Endpoints

#### Overview

IN packets are sent by the USB device controller upon IN requests from the host. All data which acknowledges or not the bank can be written when it is full.

The endpoint must be configured first.

The USBHS\_DEVEPTISRx.TXINI bit is set at the same time as USBHS\_DEVEPTIMRx.FIFOCON when the current bank is free. This triggers a PEP\_x interrupt if the Transmitted IN Data Interrupt Enable (USBHS\_DEVEPTIMRx.TXINE) bit is one.

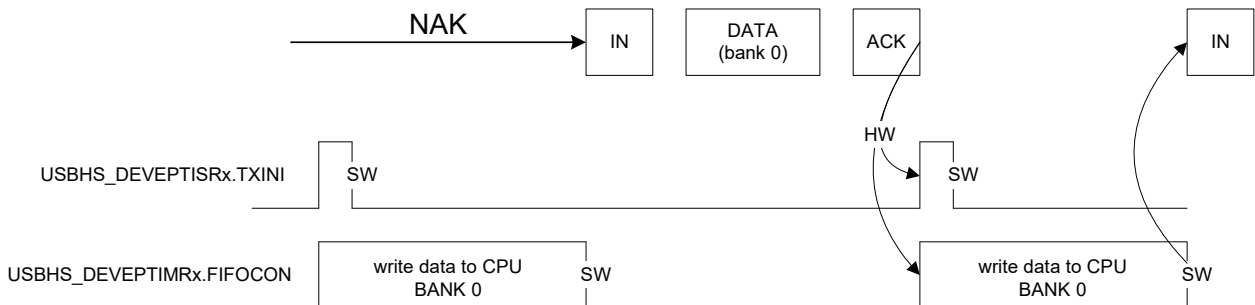

USBHS\_DEVEPTISRx.TXINI is cleared by software (by writing a one to the Transmitted IN Data Interrupt Clear bit (USBHS\_DEVEPTIDRx.TXINIC) to acknowledge the interrupt, which has no effect on the endpoint FIFO.

The user then writes into the FIFO and writes a one to the FIFO Control Clear (USBHS\_DEVEPTIDRx.FIFOCONC) bit to clear the USBHS\_DEVEPTIMRx.FIFOCON bit. This allows the USBHS to send the data. If the IN endpoint is composed of multiple banks, this also switches to the next bank. The USBHS\_DEVEPTISRx.TXINI and USBHS\_DEVEPTIMRx.FIFOCON bits are updated in accordance with the status of the next bank.

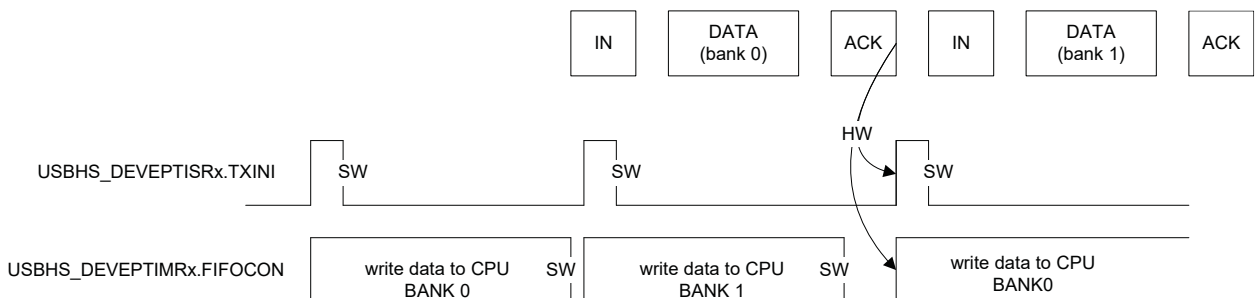

USBHS\_DEVEPTISRx.TXINI is always cleared before clearing USBHS\_DEVEPTIMRx.FIFOCON.

The USBHS\_DEVEPTISRx.RWALL bit is set when the current bank is not full, i.e., when the software can write further data into the FIFO.

**Figure 38-11. Example of an IN Endpoint with one Data Bank**

**Figure 38-12. Example of an IN Endpoint with two Data Banks**

### Detailed Description

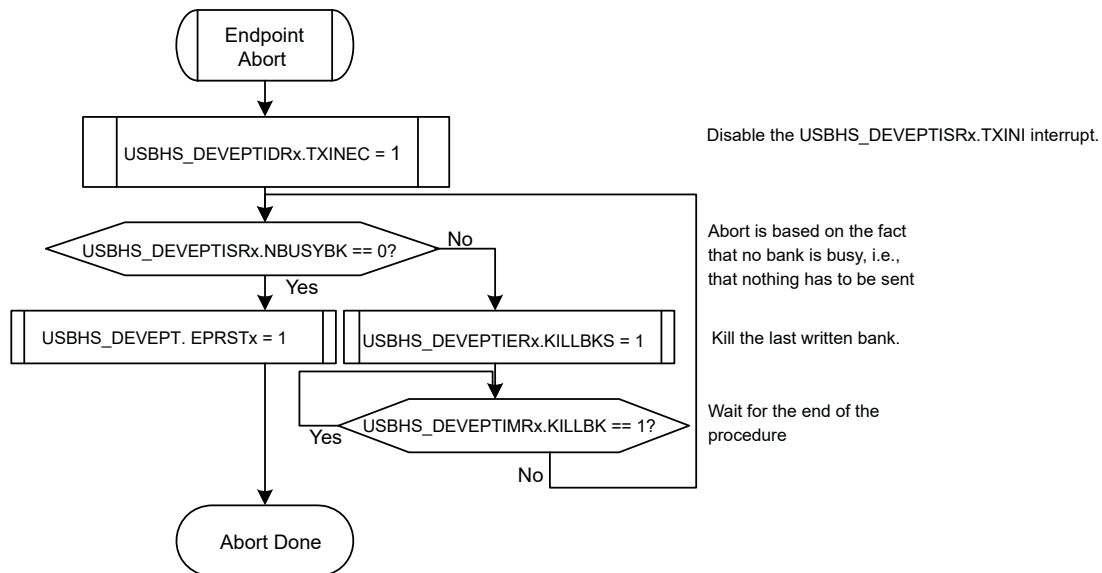

The data is written as follows:

- When the bank is empty, USBHS\_DEVEPTISRx.TXINI and USBHS\_DEVEPTIMRx.FIFOCON are set, which triggers a PEP\_x interrupt if USBHS\_DEVEPTIMRx.TXINE = 1.
- The user acknowledges the interrupt by clearing USBHS\_DEVEPTISRx.TXINI.
- The user writes the data into the current bank by using the USB Pipe/Endpoint nFIFO Data (USBFIFO nDATA) register, until all the data frame is written or the bank is full (in which case USBHS\_DEVEPTISRx.RWALL is cleared and the Byte Count (USBHS\_DEVEPTISRx.BYCT) field reaches the endpoint size).
- The user allows the controller to send the bank and switches to the next bank (if any) by clearing USBHS\_DEVEPTIMRx.FIFOCON.

If the endpoint uses several banks, the current one can be written while the previous one is being read by the host. Then, when the user clears USBHS\_DEVEPTIMRx.FIFOCON, the following bank may already be free and USBHS\_DEVEPTISRx.TXINI is set immediately.

An “Abort” stage can be produced when a zero-length OUT packet is received during an IN stage of a control or isochronous IN transaction. The Kill IN Bank (USBHS\_DEVEPTIMRx.KILLBK) bit is used to kill the last written bank. The best way to manage this abort is to apply the algorithm represented in the following figure.

**Figure 38-13. Abort Algorithm**

### 38.6.2.13 Management of OUT Endpoints

#### Overview

OUT packets are sent by the host. All data which acknowledges or not the bank can be read when it is empty.

The endpoint must be configured first.

The USBHS\_DEVEPTISRx.RXOUTI bit is set at the same time as USBHS\_DEVEPTIMRx.FIFOCON when the current bank is full. This triggers a PEP\_x interrupt if the Received OUT Data Interrupt Enable (USBHS\_DEVEPTIMRx.RXOUTE) bit is one.

USBHS\_DEVEPTISRx.RXOUTI is cleared by software (by writing a one to the Received OUT Data Interrupt Clear (USBHS\_DEVEPTICRx.RXOUTIC) bit to acknowledge the interrupt, which has no effect on the endpoint FIFO.

The user then reads from the FIFO and clears the USBHS\_DEVEPTIMRx.FIFOCON bit to free the bank. If the OUT endpoint is composed of multiple banks, this also switches to the next bank. The USBHS\_DEVEPTISRx.RXOUTI and USBHS\_DEVEPTIMRx.FIFOCON bits are updated in accordance with the status of the next bank.

USBHS\_DEVEPTISRx.RXOUTI is always cleared before clearing USBHS\_DEVEPTIMRx.FIFOCON.

The USBHS\_DEVEPTISRx.RWALL bit is set when the current bank is not empty, i.e., when the software can read further data from the FIFO.

**Figure 38-14. Example of an OUT Endpoint with one Data Bank**

**Figure 38-15. Example of an OUT Endpoint with two Data Banks**

#### Detailed Description

The data is read as follows:

- When the bank is full, USBHS\_DEVEPTISRx.RXOUTI and USBHS\_DEVEPTIMRx.FIFOCON are set, which triggers a PEP\_x interrupt if USBHS\_DEVEPTIMRx.RXOUTE = 1.
- The user acknowledges the interrupt by writing a one to USBHS\_DEVEPTICRx.RXOUTIC in order to clear USBHS\_DEVEPTISRx.RXOUTI.
- The user can read the byte count of the current bank from USBHS\_DEVEPTISRx.BYCT to know how many bytes to read, rather than polling USBHS\_DEVEPTISRx.RWALL.
- The user reads the data from the current bank by using the USBFIFOnDATA register, until all the expected data frame is read or the bank is empty (in which case USBHS\_DEVEPTISRx.RWALL is cleared and USBHS\_DEVEPTISRx.BYCT reaches zero).
- The user frees the bank and switches to the next bank (if any) by clearing USBHS\_DEVEPTIMRx.FIFOCON.

If the endpoint uses several banks, the current one can be read while the following one is being written by the host. Then, when the user clears USBHS\_DEVEPTIMRx.FIFOCON, the following bank can already be read and USBHS\_DEVEPTISRx.RXOUTI is set immediately.

In High-speed mode, the PING and NYET protocols are handled by the USBHS.

- For a single bank, a NYET handshake is always sent to the host (on Bulk-out transaction) to indicate that the current packet is acknowledged but there is no room for the next one.
- For a double bank, the USBHS responds to the OUT/DATA transaction with an ACK handshake when the endpoint accepted the data successfully and has room for another data payload (the second bank is free).

### 38.6.2.14 Underflow

This error only exists for isochronous IN/OUT endpoints. It sets the Underflow Interrupt (USBHS\_DEVEPTISRx.UNDERFI) bit, which triggers a PEP\_x interrupt if the Underflow Interrupt Enable (USBHS\_DEVEPTIMRx.UNDERFE) bit is one.

- An underflow can occur during the IN stage if the host attempts to read from an empty bank. A zero-length packet is then automatically sent by the USBHS.

- An underflow cannot occur during the OUT stage on a CPU action, since the user may only read if the bank is not empty (USBHS\_DEVEPTISRx.RXOUTI = 1 or USBHS\_DEVEPTISRx.RWALL = 1).
- An underflow can also occur during the OUT stage if the host sends a packet while the bank is already full. Typically, the CPU is not fast enough. The packet is lost.
- An underflow cannot occur during the IN stage on a CPU action, since the user may only write if the bank is not full (USBHS\_DEVEPTISRx.TXINI = 1 or USBHS\_DEVEPTISRx.RWALL = 1).

### 38.6.2.15 Overflow

This error exists for all endpoint types. It sets the Overflow interrupt (USBHS\_DEVEPTISRx.OVERFI) bit, which triggers a PEP\_x interrupt if the Overflow Interrupt Enable (USBHS\_DEVEPTIMRx.OVERFE) bit is one.

- An overflow can occur during the OUT stage if the host attempts to write into a bank which is too small for the packet. The packet is acknowledged and the USBHS\_DEVEPTISRx.RXOUTI bit is set as if no overflow had occurred. The bank is filled with all the first bytes of the packet that fit in.
- An overflow cannot occur during the IN stage on a CPU action, since the user may only write if the bank is not full (USBHS\_DEVEPTISRx.TXINI = 1 or USBHS\_DEVEPTISRx.RWALL = 1).

### 38.6.2.16 HB IsoIn Error

This error only exists for high-bandwidth isochronous IN endpoints.

At the end of the microframe, if at least one packet has been sent to the host and fewer banks than expected have been validated (by clearing the USBHS\_DEVEPTIMRx.USBHS\_DEVEPTIMRx.FIFOCON) for this microframe, it sets the USBHS\_DEVEPTISRx.HBISOINERRORI bit, which triggers a PEP\_x interrupt if the High Bandwidth Isochronous IN Error Interrupt Enable (HBISOINERRORE) bit is one.

For example, if the Number of Transactions per MicroFrame for Isochronous Endpoint (NBTRANS) field in USBHS\_DEVEPTCFGx is three (three transactions per microframe), only two banks are filled by the CPU (three expected) for the current microframe. Then, the HBISOINERRI interrupt is generated at the end of the microframe. Note that an UNDERFI interrupt is also generated (with an automatic zero-length-packet), except in the case of a missing IN token.

### 38.6.2.17 HB IsoFlush

This error only exists for high-bandwidth isochronous IN endpoints.

At the end of the microframe, if at least one packet has been sent to the host and there is a missing IN token during this microframe, the bank(s) destined to this microframe is/are flushed out to ensure a good data synchronization between the host and the device.

For example, if NBTRANS is three (three transactions per microframe) and if only the first IN token (among three) is well received by the USBHS, the last two banks are discarded.

### 38.6.2.18 CRC Error

This error only exists for isochronous OUT endpoints. It sets the CRC Error Interrupt (USBHS\_DEVEPTISRx.CRCERRI) bit, which triggers a PEP\_x interrupt if the CRC Error Interrupt Enable (USBHS\_DEVEPTIMRx.CRCERRE) bit is one.

A CRC error can occur during the OUT stage if the USBHS detects a corrupted received packet. The OUT packet is stored in the bank as if no CRC error had occurred (USBHS\_DEVEPTISRx.RXOUTI is set).

### 38.6.2.19 Interrupts

See the structure of the USB device interrupt system in [Figure 38-3](#).

There are two kinds of device interrupts: processing, i.e., their generation is part of the normal processing, and exception, i.e., errors (not related to CPU exceptions).

Global Interrupts

The processing device global interrupts are:

- Suspend (USBHS\_DEVISR.SUSP)
- Start of Frame (USBHS\_DEVISR.SOF) interrupt with no frame number CRC error - the Frame Number CRC Error (USBHS\_DEVFNUM.FNCERR) bit is zero.
- Micro Start of Frame (USBHS\_DEVISR.MSOF) with no CRC error

- End of Reset (USBHS\_DEVISR.EORST)
- Wakeup (USBHS\_DEVISR.WAKEUP)
- End of Resume (USBHS\_DEVISR.EORSM)
- Upstream Resume (USBHS\_DEVISR.UPRSM)
- Endpoint x (USBHS\_DEVISR.PEP\_x)
- DMA Channel x (USBHS\_DEVISR.DMA\_x)

The exception device global interrupts are:

- Start of Frame (USBHS\_DEVISR.SOF) with a frame number CRC error (USBHS\_DEVFNUM.FNCERR = 1)
- Micro Start of Frame (USBHS\_DEVFNUM.FNCERR.MSOF) with a CRC error  
Endpoint Interrupts

The processing device endpoint interrupts are:

- Transmitted IN Data (USBHS\_DEVEPTISRx.TXINI)
- Received OUT Data (USBHS\_DEVEPTISRx.RXOUTI)
- Received SETUP (USBHS\_DEVEPTISRx.RXSTPI)
- Short Packet (USBHS\_DEVEPTISRx.SHORTPACKET)
- Number of Busy Banks (USBHS\_DEVEPTISRx.NBUSYBK)
- Received OUT Isochronous Multiple Data (DTSEQ = MDATA & USBHS\_DEVEPTISRx.RXOUTI)
- Received OUT Isochronous DataX (DTSEQ = DATAx & USBHS\_DEVEPTISRx.RXOUTI)

The exception device endpoint interrupts are:

- Underflow (USBHS\_DEVEPTISRx.UNDERFI)
  - NAKed OUT (USBHS\_DEVEPTISRx.NAKOUTI)
  - High-Bandwidth Isochronous IN Error (USBHS\_DEVEPTISRx.HBISOINERRI)
  - NAKed IN (USBHS\_DEVEPTISRx.NAKINI)
  - High-Bandwidth Isochronous IN Flush error (USBHS\_DEVEPTISRx.HBISOFLUSHI)
  - Overflow (USBHS\_DEVEPTISRx.OVERFI)
  - STALLED (USBHS\_DEVEPTISRx.STALLEDI)
  - CRC Error (USBHS\_DEVEPTISRx.CRCERRI)
  - Transaction Error (USBHS\_DEVEPTISRx.ERRORTRANS)
- DMA Interrupts

The processing device DMA interrupts are:

- End of USB Transfer Status (USBHS\_DEVDMASTATUSx.END\_TR\_ST)
- End of Channel Buffer Status (USBHS\_DEVDMASTATUSx.END\_BF\_ST)
- Descriptor Loaded Status (USBHS\_DEVDMASTATUSx.DESC\_LDST)

There is no exception device DMA interrupt.

### 38.6.2.20 Test Modes

When written to one, the USBHS\_DEVCTRL.TSTPCKT bit switches the USB device controller to a “Test-packet” mode:

The transceiver repeatedly transmits the packet stored in the current bank. USBHS\_DEVCTRL.TSTPCKT must be written to zero to exit the Test-packet mode. The endpoint is reset by software after a Test-packet mode.

This enables the testing of rise and falling times, eye patterns, jitter, and any other dynamic waveform specifications.

The flow control used to send the packets is as follows:

- USBHS\_DEVCTRL.TSTPCKT = 1;
- Store data in an endpoint bank
- Write a zero to the USBHS\_DEVEPTIDRx.FIFOCON bit

To stop the Test-packet mode, write a zero to the USBHS\_DEVCTRL.TSTPCKT bit.

### 38.6.3 USB Host Operation

#### 38.6.3.1 Description of Pipes

For the USBHS in Host mode, the term “pipe” is used instead of “endpoint” (used in Device mode). A host pipe corresponds to a device endpoint, as described in [Figure 38-16](#) (from the USB Specification).

**Figure 38-16. USB Communication Flow**

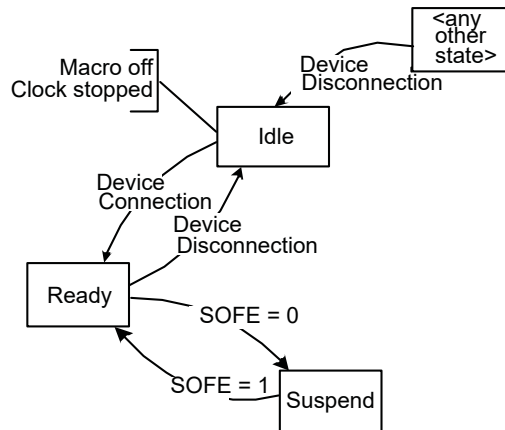

In Host mode, the USBHS associates a pipe to a device endpoint, considering the device configuration descriptors.

#### 38.6.3.2 Power-On and Reset

The following figure describes the USBHS Host mode main states.

**Figure 38-17. Host Mode Main States**

After a hardware reset, the USBHS Host mode is in the Reset state.

When the USBHS is enabled (USBHS\_CTRL.USB\_E = 1) in Host mode (USBHS\_CTRL.UIMOD = 0), it goes to the Idle state. In this state, the controller waits for a device connection with a minimal power consumption. The USB pad should be in the Idle state. Once a device is connected, the USBHS enters the Ready state, which does not require the USB clock to be activated.

The controller enters the Suspend state when the USB bus is in a “Suspend” state, i.e., when the Host mode does not generate the “Start of Frame (SOF)”. In this state, the USB consumption is minimal. The Host mode exits the Suspend state when starting to generate the SOF over the USB line.

#### 38.6.3.3 Device Detection

A device is detected by the USBHS Host mode when D+ or D- is no longer tied low, i.e., when the device D+ or D-pull-up resistor is connected. The bit USBHS\_SFR.VBUSRQS must be set to ‘1’ to enable this detection.

**Note:** The VBUS supply is not managed by the USBHS interface. It must be generated on-board.

The device disconnection is detected by the host controller when both D+ and D- are pulled down.

### 38.6.3.4 USB Reset

The USBHS sends a USB bus reset when the user writes a one to the Send USB Reset bit in the Host General Control register (USBHS\_HSTCTRL.RESET). The USB Reset Sent Interrupt bit in the Host Global Interrupt Status register (USBHS\_HSTISR.RSTI) is set when the USB reset has been sent. In this case, all pipes are disabled and de-allocated.

If the bus was previously in a “Suspend” state (the Start of Frame Generation Enable (USBHS\_HSTCTRL.SOFE) bit is zero), the USBHS automatically switches to the “Resume” state, the Host Wakeup Interrupt (USBHS\_HSTISR.HWUPI) bit is set and the USBHS\_HSTCTRL.SOFE bit is set in order to generate SOFs or micro SOFs immediately after the USB reset.

At the end of the reset, the user should check the USBHS\_SR.SPEED field to know the speed running according to the peripheral capability (LS.FS/HS).

### 38.6.3.5 Pipe Reset

A pipe can be reset at any time by writing a one to the Pipe x Reset (USBHS\_HSTPIP.PRSTx) bit. This is recommended before using a pipe upon hardware reset or when a USB bus reset has been sent. This resets:

- the internal state machine of the pipe,
- the receive and transmit bank FIFO counters,
- all the registers of the pipe (USBHS\_HSTPIPCFGx, USBHS\_HSTPIPISRx, USBHS\_HSTPIPIMRx), except its configuration (USBHS\_HSTPIPCFGx.ALLOC, USBHS\_HSTPIPCFGx.PBK, USBHS\_HSTPIPCFGx.PSIZE, USBHS\_HSTPIPCFGx.PTOKEN, USBHS\_HSTPIPCFGx.PTYPE, USBHS\_HSTPIPCFGx.PEPNUM, USBHS\_HSTPIPCFGx.INTFRQ) and its Data Toggle Sequence field (USBHS\_HSTPIPISRx.DTSEQ).

The pipe configuration remains active and the pipe is still enabled.

The pipe reset may be associated with a clear of the data toggle sequence. This can be achieved by setting the Reset Data Toggle bit in the Pipe x Control register (USBHS\_HSTPIPIMRx.RSTDT) (by writing a one to the Reset Data Toggle Set bit in the Pipe x Control Set register (USBHS\_HSTPIPIERx.RSTDTS)).

In the end, the user has to write a zero to the USBHS\_HSTPIP.PRSTx bit to complete the reset operation and to start using the FIFO.

### 38.6.3.6 Pipe Activation

The pipe is maintained inactive and reset (see "Pipe Reset" for more details) as long as it is disabled (USBHS\_HSTPIP.PENx = 0). The Data Toggle Sequence field (USBHS\_HSTPIPISRx.DTSEQ) is also reset.

The algorithm represented in the following figure must be followed to activate a pipe.

**Figure 38-18. Pipe Activation Algorithm**

As long as the pipe is not correctly configured (USBHS\_HSTPIPISRx.CFGOK = 0), the controller cannot send packets to the device through this pipe.

The USBHS\_HSTPIPIRx.CFGOK bit is only set if the configured size and number of banks are correct as compared to their maximal allowed values for the pipe (see the [Description of USB Pipes/Endpoints](#) table) and to the maximal FIFO size (i.e., the DPRAM size).

See "DPRAM Management" for additional information.

Once the pipe is correctly configured (USBHS\_HSTPIPIRx.CFGOK = 1), only the USBHS\_HSTPIPCFGx.PTOKEN and USBHS\_HSTPIPCFGx.INTFRQ fields can be written by software. USBHS\_HSTPIPCFGx.INTFRQ is meaningless for non-interrupt pipes.

When starting an enumeration, the user gets the device descriptor by sending a GET\_DESCRIPTOR USB request. This descriptor contains the maximal packet size of the device default control endpoint (bMaxPacketSize0) and the user reconfigures the size of the default control pipe with this size parameter.

### 38.6.3.7 Address Setup

Once the device has answered the first host requests with the default device address 0, the host assigns a new address to the device. The host controller has to send a USB reset to the device and to send a SET\_ADDRESS (addr) SETUP request with the new address to be used by the device. Once this SETUP transaction is over, the user writes the new address into the USB Host Address for Pipe x field in the USB Host Device Address register (HSTADDR.HSTADDRPx). All the following requests on all pipes are then performed using this new address.

When the host controller sends a USB reset, the HSTADDRPx field is reset by hardware and the following host requests are performed using the default device address 0.

### 38.6.3.8 Remote Wakeup

The controller Host mode enters the Suspend state when the USBHS\_HSTCTRL.SOFE bit is written to zero. No more "Start of Frame" is sent on the USB bus and the USB device enters the Suspend state 3 ms later.

The device awakes the host by sending an Upstream Resume (Remote Wakeup feature). When the host controller detects a non-idle state on the USB bus, it sets the Host Wakeup interrupt (USBHS\_HSTISR.HWUPI) bit. If the non-idle bus state corresponds to an Upstream Resume (K state), the Upstream Resume Received Interrupt (USBHS\_HSTISR.RXRSMI) bit is set. The user has to generate a Downstream Resume within 1 ms and for at least 20 ms by writing a one to the Send USB Resume (USBHS\_HSTCTRL.RESUME) bit. It is mandatory to write a one to USBHS\_HSTCTRL.SOFE before writing a one to USBHS\_HSTCTRL.RESUME to enter the Ready state, otherwise USBHS\_HSTCTRL.RESUME has no effect.

### 38.6.3.9 Management of Control Pipes

A control transaction is composed of three stages:

- SETUP
- Data (IN or OUT)
- Status (OUT or IN)

The user has to change the pipe token according to each stage.

For the control pipe only, each token is assigned a specific initial data toggle sequence:

- SETUP: Data0
- IN: Data1
- OUT: Data1

### 38.6.3.10 Management of IN Pipes

IN packets are sent by the USB device controller upon IN requests from the host. All data which acknowledges or not the bank can be read when it is empty.

The pipe must be configured first.

When the host requires data from the device, the user has to first select the IN Request mode with the IN Request Mode bit in the Pipe x IN Request register (USBHS\_HSTPIPIRQx.INMODE):

- When USBHS\_HSTPIPIRQx.INMODE = 0, the USBHS performs (INRQ + 1) IN requests before freezing the pipe.
- When USBHS\_HSTPIPIRQx.INMODE = 1, the USBHS performs IN requests endlessly when the pipe is not frozen by the user.

The generation of IN requests starts when the pipe is unfrozen (the Pipe Freeze (USBHS\_HSTPIIMRx.PFREEZE) field in USBHS\_HSTPIIMRx is zero).

The Received IN Data Interrupt (USBHS\_HSTPIISRx.RXINI) bit is set at the same time as the FIFO Control (USBHS\_HSTPIIMRx.FIFOCON) bit when the current bank is full. This triggers a PEP\_x interrupt if the Received IN Data Interrupt Enable (USBHS\_HSTPIIMRx.RXINE) bit is one.

USBHS\_HSTPIISRx.RXINI is cleared by software (by writing a one to the Received IN Data Interrupt Clear bit in the Host Pipe x Clear register (USBHS\_HSTPIIDRx.RXINIC)) to acknowledge the interrupt, which has no effect on the pipe FIFO.

The user then reads from the FIFO and clears the USBHS\_HSTPIIMRx.FIFOCON bit (by writing a one to the FIFO Control Clear (USBHS\_HSTPIIDRx.FIFOCONC) bit) to free the bank. If the IN pipe is composed of multiple banks, this also switches to the next bank. The USBHS\_HSTPIISRx.RXINI and USBHS\_HSTPIIMRx.FIFOCON bits are updated in accordance with the status of the next bank.

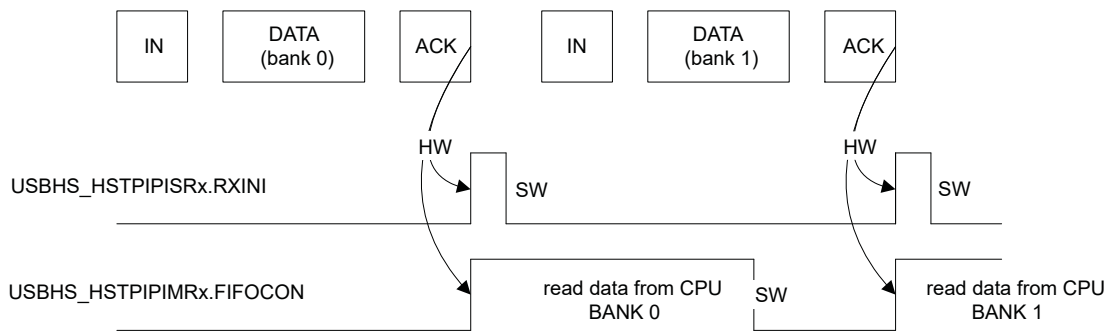

USBHS\_HSTPIISRx.RXINI is always cleared before clearing USBHS\_HSTPIIMRx.FIFOCON.

The Read/Write Allowed (USBHS\_HSTPIISRx.RWALL) bit is set when the current bank is not empty, i.e., when the software can read further data from the FIFO.

**Figure 38-19. Example of an IN Pipe with one Data Bank**

**Figure 38-20. Example of an IN Pipe with two Data Banks**

### 38.6.3.11 Management of OUT Pipes

OUT packets are sent by the host. All data which acknowledges or not the bank can be written when it is full.

The pipe must be configured and unfrozen first.

The Transmitted OUT Data Interrupt (USBHS\_HSTPIISRx.TXOUTI) bit is set at the same time as USBHS\_HSTPIIMRx.FIFOCON when the current bank is free. This triggers a PEP\_x interrupt if the Transmitted OUT Data Interrupt Enable (USBHS\_HSTPIIMRx.TXOUTE) bit is one.

USBHS\_HSTPIISRx.TXOUTI is cleared by software (by writing a one to the Transmitted OUT Data Interrupt Clear (USBHS\_HSTPIIDRx.TXOUTIC) bit) to acknowledge the interrupt, which has no effect on the pipe FIFO.

The user then writes into the FIFO and clears the USBHS\_HSTPIIDRx.FIFOCON bit to allow the USBHS to send the data. If the OUT pipe is composed of multiple banks, this also switches to the next bank. The USBHS\_HSTPIISRx.TXOUTI and USBHS\_HSTPIIMRx.FIFOCON bits are updated in accordance with the status of the next bank.

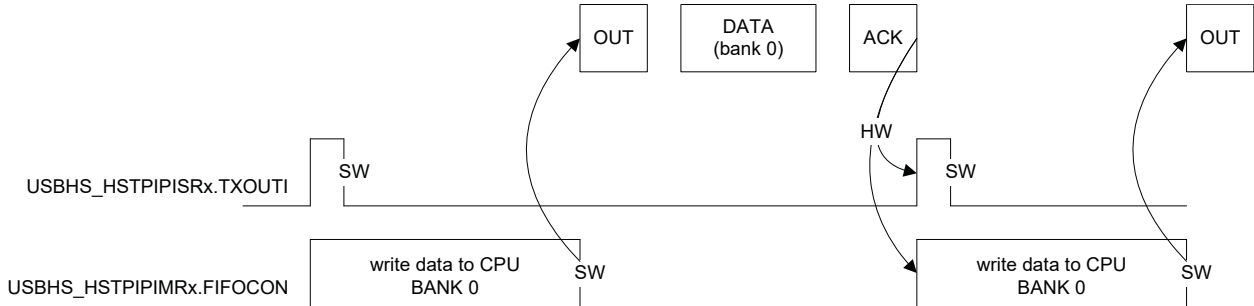

USBHS\_HSTPIISRx.TXOUTI is always cleared before clearing USBHS\_HSTPIIMRx.FIFOCON.

The USBHS\_HSTPIPIISRx.RWALL bit is set when the current bank is not full, i.e., when the software can write further data into the FIFO.

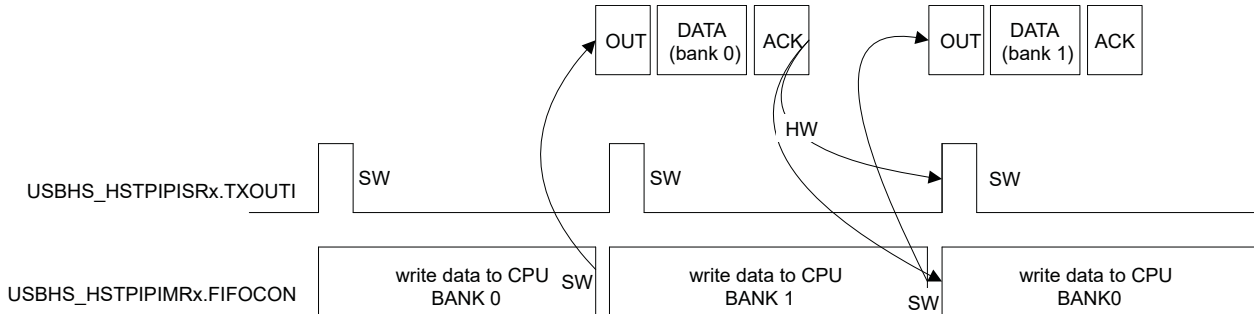

**Notes:**

1. If the user decides to switch to the Suspend state (by writing a zero to the USBHS\_HSTCTRL.SOFE bit) while a bank is ready to be sent, the USBHS automatically exits this state and the bank is sent.
2. In High-speed operating mode, the host controller automatically manages the PING protocol to maximize the USB bandwidth. The user can tune the PING protocol by handling the Ping Enable (PINGEN) bit and the Interval Parameter for the Bulk-Out/Ping Transaction (BINTERVAL) field in USBHS\_HSTPIPCFGx. See the [Host Pipe x Configuration Register](#) for additional information.

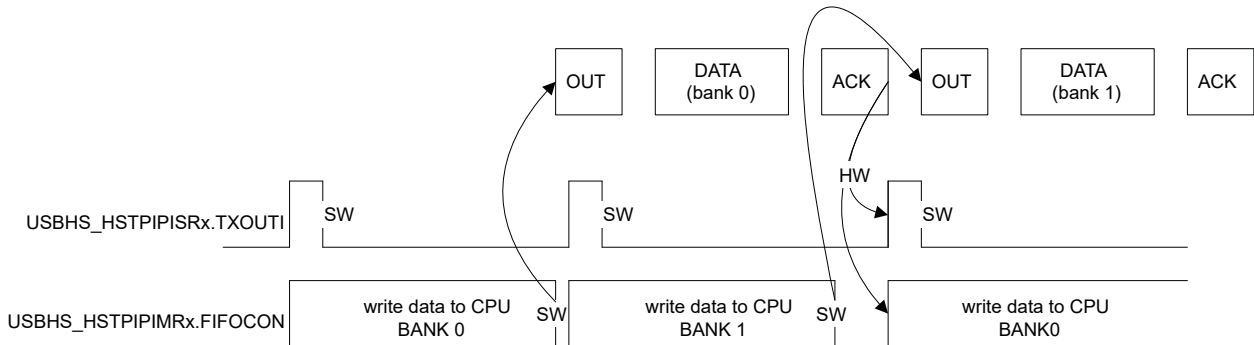

**Figure 38-21. Example of an OUT Pipe with one Data Bank**

**Figure 38-22. Example of an OUT Pipe with two Data Banks and no Bank Switching Delay**

**Figure 38-23. Example of an OUT Pipe with two Data Banks and a Bank Switching Delay**

**38.6.3.12 CRC Error**

This error exists only for isochronous IN pipes. It sets the CRC Error Interrupt (USBHS\_HSTPIPIISRx.CRCERRI) bit, which triggers a PEP\_x interrupt if then the CRC Error Interrupt Enable (USBHS\_HSTPIPIIMRx.CRCERRE) bit is one.

A CRC error can occur during IN stage if the USBHS detects a corrupted received packet. The IN packet is stored in the bank as if no CRC error had occurred (USBHS\_HSTPIPIISRx.RXINI is set).

**38.6.3.13 Interrupts**

See the structure of the USB host interrupt system on [Figure 38-3](#).

There are two kinds of host interrupts: processing, i.e., their generation is part of the normal processing, and exception, i.e., errors (not related to CPU exceptions).

### Global Interrupts

The processing host global interrupts are:

- Device Connection (USBHS\_HSTISR.DCONNI)
- Device Disconnection (USBHS\_HSTISR.DDISCI)
- USB Reset Sent (USBHS\_HSTISR.RSTI)
- Downstream Resume Sent (USBHS\_HSTISR.RSMEDI)
- Upstream Resume Received (USBHS\_HSTISR.RXRSMI)
- Host Start of Frame (USBHS\_HSTISR.HSOFI)
- Host Wakeup (USBHS\_HSTISR.HWUPI)
- Pipe x (USBHS\_HSTISR.PEP\_x)
- DMA Channel x (USBHS\_HSTISR.DMAxINT)

There is no exception host global interrupt.

### Pipe Interrupts

The processing host pipe interrupts are:

- Received IN Data (USBHS\_HSTPIISRx.RXINI)
- Transmitted OUT Data (USBHS\_HSTPIISRx.TXOUTI)
- Transmitted SETUP (USBHS\_HSTPIISRx.TXSTPI)
- Short Packet (USBHS\_HSTPIISRx.SHORTPACKETI)
- Number of Busy Banks (USBHS\_HSTPIISRx.NBUSYBK)

The exception host pipe interrupts are:

- Underflow (USBHS\_HSTPIISRx.UNDERFI)
  - Pipe Error (USBHS\_HSTPIISRx.PERRI)
  - NAKed (USBHS\_HSTPIISRx.NAKEDI)
  - Overflow (USBHS\_HSTPIISRx.OVERFI)
  - Received STALLed (USBHS\_HSTPIISRx.RXSTALLDI)
  - CRC Error (USBHS\_HSTPIISRx.CRCERRI)
- DMA Interrupts

The processing host DMA interrupts are:

- The End of USB Transfer Status (USBHS\_HSTDMASTATUSx.END\_TR\_ST)
- The End of Channel Buffer Status (USBHS\_HSTDMASTATUSx.END\_BF\_ST)
- The Descriptor Loaded Status (USBHS\_HSTDMASTATUSx.DESC\_LDST)

There is no exception host DMA interrupt.

## 38.6.4 USB DMA Operation

USB packets of any length may be transferred when required by the USBHS. These transfers always feature sequential addressing. Such characteristics mean that in case of high USBHS throughput, both AHB ports benefit from “incrementing burst of unspecified length” since the average access latency of AHB Clients can then be reduced.

The DMA uses word “incrementing burst of unspecified length” of up to 256 beats for both data transfers and channel descriptor loading. A burst may last on the AHB busses for the duration of a whole USB packet transfer, unless otherwise broken by the AHB arbitration or the AHB 1-Kbyte boundary crossing.

Packet data AHB bursts may be locked on a DMA buffer basis for drastic overall AHB bus bandwidth performance boost with paged memories. This prevents large AHB bursts from being broken in case of conflict with other AHB bus Hosts, thus avoiding access latencies due to memory row changes. This means up to 128 words single cycle unbroken AHB bursts for bulk pipes/endpoints and 256 words single cycle unbroken bursts for isochronous pipes/endpoints. This maximal burst length is then controlled by the lowest programmed USB

Pipe/Endpoint Size (USBHS\_HSTPIPCFGx.PSIZE / USBHS\_DEVEPTCFGx.EPSIZE) and the Buffer Byte Length (USBHS\_HSTDMACONTROLx.BUFF\_LENGTH / USBHS\_DEVDMACONTROLx.BUFF\_LENGTH) fields.

The USBHS average throughput can reach nearly 480 Mbps. Its average access latency decreases as burst length increases due to the zero wait-state side effect of unchanged pipe/endpoint. Word access allows reducing the AHB bandwidth required for the USB by four, as compared to native byte access. If at least 0 wait-state word burst capability is also provided by the other DMA AHB bus Clients, each DMA AHB bus needs less than 60% bandwidth allocation for full USB bandwidth usage at 33 MHz, and less than 30% at 66 MHz.

**Figure 38-24. Example of a DMA Chained List**

### 38.6.5 USB DMA Channel Transfer Descriptor

The DMA channel transfer descriptor is loaded from the memory. The following structures apply:

Offset 0:

- The address must be aligned: 0xXXXX0
- Next Descriptor Address Register: USBHS\_xxxDMANXTDSCx

Offset 4:

- The address must be aligned: 0xXXXX4
- DMA Channelx Address Register: USBHS\_xxxDMAADDRESSx

Offset 8:

- The address must be aligned: 0xXXXX8
- DMA Channelx Control Register: USBHS\_xxxDMACONTROLx

To use the DMA channel transfer descriptor, fill the structures with the correct values (as described in the following pages), then write directly in USBHS\_xxxDMANXTDSCx the address of the descriptor to be used first.

Then write 1 in the USBHS\_xxxDMACONTROLx.LDNXT\_DSC bit (load next channel transfer descriptor). The descriptor is automatically loaded upon pipe x / endpoint x request for packet transfer.

# SAM E70/S70/V70/V71

## USB High-Speed Interface (USBHS)

### 38.7 Register Summary

| Offset              | Name                 | Bit Pos. | 7            | 6         | 5           | 4         | 3            | 2      | 1      | 0       |  |
|---------------------|----------------------|----------|--------------|-----------|-------------|-----------|--------------|--------|--------|---------|--|
| 0x00                | USBHS_DEVCTRL        | 7:0      | ADDEN        | UADD[6:0] |             |           |              |        |        |         |  |
